Digital-to-Analog Converters with Serial Interface
## CMOS LSI

The MC144110 and MC144111 are low–cost 6–bit D/A converters with serial interface ports to provide communication with CMOS microprocessors and microcomputers. The MC144110 contains six static D/A converters; the MC144111 contains four converters.

Due to a unique feature of these DACs, the user is permitted easy scaling of the analog outputs of a system. Over a 5 to 15 V supply range, these DACs may be directly interfaced to CMOS MPUs operating at 5 V.

- Direct R–2R Network Outputs
- Buffered Emitter–Follower Outputs
- Serial Data Input
- Digital Data Output Facilitates Cascading
- Direct Interface to CMOS μP
- Wide Operating Voltage Range: 4.5 to 15 V
- Wide Operating Temperature Range: 0 to 85°C
- Software Information is Contained in Document M68HC11RM/AD

* Maximum Ratings are those values beyond which damage to the device may occur.

This device contains protection circuitry to guard against damage due to high static voltages or electric fields; however, it is advised that precautions be taken to avoid application of voltage higher than maximum rated voltages to this high–impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq$ (V_{in} or V_{out}) $\leq V_{DD}$.

Unused inputs must always be tied to an appropriate logic voltage level (e.g., either V_{SS} or V_{DD}).

LINEARITY ERROR (integral linearity). A measure of how straight a device's transfer function is, it indicates the worst–case deviation of linearity of the actual transfer function from the best–fit straight line. It is normally specified in parts of an LSB.

INPUTS

D_{in}
Data Input

Six–bit words are entered serially, MSB first, into digital data input, D_{in}. Six words are loaded into the MC144110 during each D/A cycle; four words are loaded into the MC144111.

The last 6–bit word shifted in determines the output level of pins Q1 Out and R1 Out. The next–to–last 6–bit word affects pins Q2 Out and R2 Out, etc.

$\overline{ENB}$
Negative Logic Enable

The $\overline{ENB}$ pin must be low (active) during the serial load. On the low–to–high transition of $\overline{ENB}$, data contained in the shift register is loaded into the latch.

CLK
Shift Register Clock

Data is shifted into the register on the high–to–low transition of CLK. CLK is fed into the D–input of a transparent latch, which is used for inhibiting the clocking of the shift register when $\overline{ENB}$ is high.

The number of clock cycles required for the MC144110 is usually 36. The MC144111 usually uses 24 cycles. See Table 1 for additional information.

OUTPUTS

D_{out}
Data Output

The digital data output is primarily used for cascading the DACs and may be fed into D_{in} of the next stage.

R1 Out through Rn Out
Resistor Network Outputs

These are the R–2R resistor network outputs. These outputs may be fed to high–impedance input FET op amps to bypass the on–chip bipolar transistors. The R value of the resistor network ranges from 7 to 15 kΩ.

Q1 Out through Qn Out
NPN Transistor Outputs

Buffered DAC outputs utilize an emitter–follower configuration for current–gain, thereby allowing interface to low–impedance circuits.

SUPPLY PINS

V_{SS}
Negative Supply Voltage

This pin is usually ground.

V_{DD}
Positive Supply Voltage

The voltage applied to this pin is used to scale the analog output swing from 4.5 to 15 V p–p.
