Using the TP4056: There's a right way, and a wrong way for safe charging of Lithium Ion batteries with this chip!

TP4056: A LiPo battery charger IC (page 1, page 2 is here).

- An easy to use **battery charger** chip.
- Charging current from **130mA to 1A**.

• Learn to use it the **correct way**.

Find out how to correct its operation for Safe In-Circuit Charging.

The TP4056 chip is a lithium Ion battery charger for a single cell battery, protecting the cell from over and under charging. It has two status outputs indicating charging in progress, and charging complete. It also has a programmable charge current of up to 1A.

You can use it to charge batteries directly from a USB port since the working input voltage range is 4V ~ 8V. However, remember the maximum current from a USB port is 500mA. There are two types of common breakout boards for this chip:

- One with only the charger chip on board. One with three chips on board.

and 8205A dual MOSFET - bottom right).

Here you are looking at the 3 chip breakout board (TP4056 - middle, DW01A - top right,

How to use the TP4056 breakout board.

- How to use the TP4056 safely.
- How the DW01A works on the TP4056 breakout board.
- **Note:** You need to <u>change the current programming resistor</u> on the breakout

How to set temperature limits using the TP4056 TEMP input.

a 1Ah (1000mAh) battery. Note: Follow this link to learn how to use the DW01A correctly.

board to match the lithium battery you are using - the default is 1.2k which is for

Lithium batteries can be dangerous if not charged properly and that's why the TP4056 is useful as it stops over voltage and current charging by detecting specific voltage

conditions. Warning

There are a lot of circuits out there that show the use of the TP4056 as

both a charger and a load driver - Not Good. If a load is attached to the battery while charging, then the TP4056 may not detect when the charge current has fallen to C/10. So it could continue charging - this could be dangerous. You should never use the TP4056 as a charger and as a load driver at the **same time**. When charging the battery, switch off the load, and when loading the

Lithium batteries can not absorb overcharge - the current must be cut off after charging. If not there could be thermal runaway.

battery, switch off the charger. Alternatively use a PMOSFET, a resistor and a

Constant Current / Constant voltage charging method. • C/10 Charge termination.

TP4056 Features

• 2.9V trickle charge threshold (for deeply discharged batteries). • Upper charge stop voltage: 4.2V.

Schottky diode (See page 2 on how to do this).

- Soft start inrush current limit.
- Automatic recharge (keeps batteries optimally charged when connected to a charger).

TP4056 module Datasheet Download the TP4056 Datasheet here.

TP4056 Specifications

Parameter

Value

Voltage Supply (Vs)	4V0 ~ 8V0			
Charge Voltage termination (accuracy)	4.2V(1.5%)			
Supply current (Rprog=1.2k: 1A chrg)	150uA (typ)			
Supply current (Chrg ended/ shutdown)	55uA (typ)			
Ibat (Rprog=1.2k: 1A chrg)	1050mA (max)			
Ibat (Stand by mode; $Vbat = 4.2V$)	-6uA (max)			
Vtrckl(Rprog=1.2k: Vbat:rising)	2.9V (typ)			
Itrckl (Rprog=1.2k: Vbat <vtrckl)<="" td=""><td>140mA max)</td></vtrckl>	140mA max)			
Vtrhsy(Rprog=1.2k)	80mV (typ)			
Operating temperature	-40°C ~ 85°C			
[trckl = Trickle charge, trhsy = Trickle Charge Hysteresis]				

TP4056 Current Programming Resistor The programming resistor (R3 or Rprog) is set to 1k2 which provides 1A programming

charge rate or 1C. If your battery is not 1000mAh (1Ah), then you need to remove R3 and replace it with the correct one following the information in the table on the right.

TP4056 Status indicator LEDs The table shows the state of LEDs for various charging states:

TP4056 Charger Module Schematic				
This is the schematic of the popular breakout board with label 03962A this shows the				

TP4056 pinout for the breakout board.

TP4056 Connections The following diagram shows a typical setup (from the datasheet). The block diagram also

[Source:www.sunrom.com/p/lithum-battery-charger-with-protection-microusb]

input and take the output voltage from OUT+ and OUT- to your circuit.

shows the TP456 pinout for the 8 pin SMD device.

When charging a battery using the above board connect the battery to B+ and B- and

disconnect OUT+ and OUT- from your circuit. When using the battery disconnect the 5V

The TP4056 does not give you reverse polarity protection so if you wire up the battery the wrong way round then you'll get smoke! Actually, there is no TP4056 reverse polarity protection and the <u>DW01A_battery_protection</u> IC (on the breakout board) is being used in the wrong way (or not in the best way)! If used correctly the DW01A does provide reverse polarity protection for a battery.

Here you can see the two status LEDs (CHRGn, STDBYn), Battery connection (BAT), Current control connection (PROG) and TEMP connection. Some LI batteries have an

internal thermistor that you can connect as shown above. In the breakout boards

available generally TEMP is not used and connected to Ground.

TP4056 reverse polarity protection

Note: Follow this link to learn how to use the DW01A correctly.

DW01A Battery Protector Chip

On some breakout boards there are an extra 2 chips. One is the DW01A and the other is a dual N Channel MOSFET required by the DW01A chip.

This chip provides battery protection but it is not used in the right way on this board and

so only provides short circuit protection (and over current protection). It should provide

all of the following: Charger input protection

The CS pin is connected to the negative terminal of the charger input (via a 1kA¢ resistor) and performs the following functions:

Reverse charger detection (overstress high current?).

Battery monitoring VCC and GND are connected across the battery where two voltages are detected:

Short Circuit detector.

Over current detector.

Charger Detector.

- Overcharge Detector (battery voltage too high).
- Overdischarge Detector (battery voltage too low). DW01A and TP4056 breakout Board

On the breakout board, the chip is soldered to the TP4056 so this can never be connected the wrong way round at the "charger input". At the other side the DW01A does not protect from connecting the battery the wrong way round!

This chip will not activate for battery voltage level problems (unless the TP4056 fails) since the TP4056:

 Stops discharging at voltages below 2.9V; Here trickle charge activates. The DW01A threshold is \sim 2.4V; So it will never activate. Stops charging at voltages above 4.2V. The DW01A threshold is \sim 4.3V; So it will never activate.

The only function that will operate is the overcurrent protection and short circuit protection. These will activate at around 3A when using the 8205A dual Mosfet.

Continued... This article continues on page 2, where you can find out how to use the TP4056 in the

correct way (most circuits are not correct).

TP4056 Part 2

This page is a continuation from page 1 here.

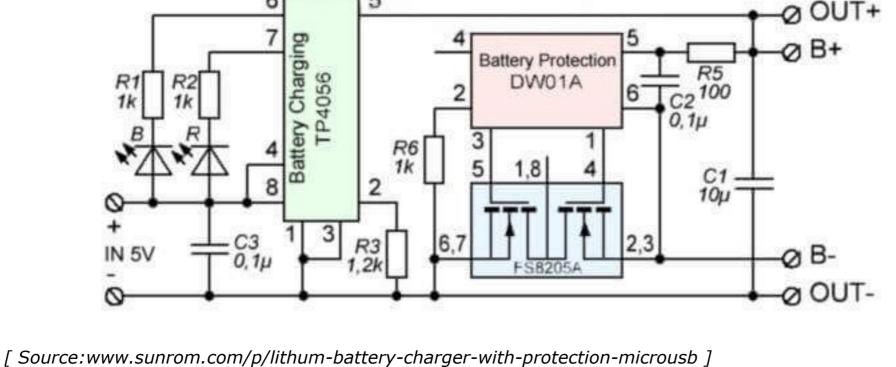

This page shows you Two aspects of using the TP4056:

1. How to use the TP4056 in the correct way (load disconnection during charging). 2. Automatic charge stop on internal battery temperature limit.

This is the schematic of the popular breakout board with label 03962A this shows the TP4056 pinout for the breakout board.

TP4056 Power Sharing Problem

Ø OUT+

capacity in mAh.

If you have a load connected to the battery then this will change the current detected so the TP4056 may never terminate the charging process!

Using 3 Components to achieve safe charging A way around this problem is to use a switching circuit employing a P Channel MOSFET -

PMOSFET disconnects the battery from the load. The TP4056 still charges the battery but

without a load. Power to the load is supplied from the power source directly.

this is sometimes called load sharing or automatic power path control. it is a controlled switch that disconnects the battery when external power is applied. The idea is that when a power source is connected to the Battery charger chip, the

the battery. With this configuration the TP4056 can safely charge the battery with the load connected, as the battery is isolated from the load during external power application. PMOSFET power Sharing

The following diagrams show how the PMOSFET is used for power sharing. To turn ON the PMOSFET, the Gate must be negative (<V $_{GS(th)}$) w.r.t the Source. To turn OFF the PMOSFET, the Gate must higher than $V_{GS(th)}$ w.r.t the Source.

PMOSFET ON (Just the battery)

Note: $V_{GS(th)}$ is the threshold voltage of the MOSFET.

There is no input voltage to the charger circuit or the MOSFET. Here the gate of Q1 is low (pulled down by R_{PULL}) and the PMOSFET is on, so current flows from the battery to the load.

State of D1 No Input Power

State of Q1 No Input Power

-2.3V. e.g. -1.0 \sim -1.5 would be good.

internal resistance of Q1 (R_{DS}).

4.2V.

and Vbat-0.6V appears at the negative side of D1. Since the other side of D1 is pulled to ground D1 is reversed biased so no current flows through it. So it can be ignored (except for leakage current = small so ignore anyway - but some Schottky diodes may leak a lot requiring lower R_{PULL}).

[Source: Microchip application note AN1149]

When the battery is connected to the circuit, the parasitic diode (of Q1) is forward biased

The cathode of D1 is also connected to the Source of Q1. The gate of Q1 is also pulled to

To see what is going on here start with the battery with no external power supplied:

As long as V_{GS} is more negative than the Gate Threshold voltage of Q1 ($V_{GS(TH)}$), Q1 is on and conducts current between the Drain and the Source. So the Gate to Source threshold voltage of Q1 ($V_{GS(TH)}$) must be better than: -(2.9-0.4) = -2.5V

0V. Typically -1.3V is good. (See the table below of suitable PMOSFETS).

Note: The TP4056 will trickle charge a very deeply discharged battery where Vbat is < 2.9V until it reaches that 2.9V so you will want a threshold voltage better than

Note: R_{DS} is an important parameter here - it's the internal resistance of the PMOSFET from Drain to source i.e. the internal resistance of the MOSFET. As more current is drawn by the load, more voltage is dropped across R_{DS}. So the

Once Q1 is on the parasitic diode is bypassed and Vbat is connected to the load via the

PMOSFET OFF (Power source connected)

Here the gate of Q1 is high and the PMOSFET is off, so the battery is isolated from the load. The power source drives current through the Schottky diode (D1) to the load. At the

same time, the battery is charged but in isolation from the load.

therefore the MOSFET is off.

Since the Gate is equal to $Vin (\sim 5V)$ and the diode drops 0.4V, Vgs is positive by 0.4V,

@Vth=-2.5

FET)

You would probably want to avoid the higher $R_{\text{DS}(\text{ON})}$ device as you loose volts when drawing more current.
Example of a Schottky Diode MBRS130LT3: Forward voltage drop of 0.395V (max for 1A and @ 25°C).
Note: The Schottky diode will heat up when the charger is externally powered. The Power used depends on the load attached to the output - current through it and voltage drop across it.
An alternative to the Schottky diode is to use the 2 nd PMOSFET in the IRF7329 above to replace the diode. This would need controlling using a microcontroller or using the status outputs of the TP4056 (see the LTC4056 datasheet - which is a different chip but provides a design reference).

The diagram below (from the datasheet) shows use of the TEMP input with a battery that includes a NTC (Negative Temperature Coefficient) Thermistor:

Using this input in your own designs ensures safer charging but you need a battery with an internal thermistor. The TP4056 can then shut down charging if the temperature inside the battery becomes too high or too low.

R1 and R2 are not specified in the datasheet so you have to work these out based on the

" If TEMP pin's voltage is below 45% or above 80% of supply voltage VIN for more than 0.15S, this means that battery's temperature is too high or too low,

The TEMP input is used to disable charging if the internal battery temperature becomes

too high or too low. It is usually grounded at the chip pin on breakout board.

Working out R1 and R2 for the TP4056

Recommended operating temperature

Temperature Limit Design Calculations

For 45°C the thermistor resistance is about 4k2. For 5°C the thermistor resistance is about 26k.

charging at even tighter temperature limits.

charging is suspended. " [source TP4056 Datasheet]

Assumption:

operation.

down.

and

thermistor specification in your specific battery. From the datasheet:

Battery University recommends charging only from 5°C to 45°C.

Note: Use these calculations at your own risk. Also you must use the battery

The battery's internal NTC thermistor reads 10k at 25°C and has a Beta value of 3950 (this is for a type MF52 thermistor). **Note:** You can charge outside these temperatures (5°C ~ 45°C) but with a more complex chip than the TP4056, one that reduces charge/voltage at outside these temperatures but never charge below 0°C.

Warning: This is just an example calculation. Always use the battery

manufacturer's data on the thermistor for operational use. Also other standards suggest

You can see that R1 is pulled high and R2 is pulled low and and they connect to one side

So R2 is in parallel with R_{NTC} . This parallel resistance forms the lower half of a voltage

divider with R1. As temperature increases so R_{NTC} falls pulling the TEMP input voltage

The trick is to select resistors that give you the correct %output when R_{NTC} changes

It can be a bit tricky selecting the correct resistors but remember the battery will heat up as current is drawn so the most important parameter is the high temperature cut off. You

You can scratch your head trying to figure out algorithms for a while as there are three variables to change and with two set points to get right. But an easier way is to write a program for a brute force method. R_{NTC} is in parallel with R2. Therefore:

 $R_{PARALLEL} = R_{P} = (R_{NTC} * R2) / (R_{NTC} + R2)$

The closest Standard resistors (E48) are:

r1 4780 r2 86600 Rntc1 4.2e3 Rntc2 26e3

These standard values result in the following ratios:

(E48) R2 = 86600

(E48) R1 = 4870

Inputs for MF52 (B=3950)

Conclusions The TP4056 is designed for charging control of a Lithium Ion/Poly battery pack that you charge at home, and take out with you, just in case you run out of charge when you are out.

battery pack. You always charge the phone directly from the charger socket at home and you can't charge the battery pack when you are out. This is the exact problem the TP4056 was designed to solve and it should not both charge

However, I have never heard of any problems in using the breakout board as it is commonly used - as a charger and power source at the same time. But it is far safer to tack on three components as discussed in this page.

If you are looking for Part 1 of this article it is here.
