### MAX77962

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### **General Description**

The MAX77962 is a high-performance wide-input 3.2A buck-boost charger with a Smart Power Selector<sup>TM</sup> and operates as a reverse buck without an additional inductor, allowing the IC to power USB On-the-Go (OTG) accessories. The device integrates low-loss power switches, and provides small solution size, high-efficiency, low heat, and fast battery charging. The reverse buck has true-load disconnect and is protected by an adjustable output current limit. The device is highly flexible and programmable through  $I^2C$  configuration or autonomously through resistor configuration.

The battery charger includes a Smart Power Selector to accommodate a wide range of battery sizes and system loads. The Smart Power Selector allows the system to start up gracefully when an input source is available even when the battery is deeply discharged (dead battery) or missing. For battery safety/authentication reasons, the IC can be configured to keep charging disabled, and allow the DC-DC to switch and regulate the SYS voltage. The system processor can later enable charging using the appropriate I<sup>2</sup>C commands. Alternatively, the IC can be configured to automatically start charging.

### **Benefits and Features**

- 3.5V to 23V Input Operating Range, 30V<sub>DC</sub> Withstand Voltage
- Reverse Leakage Protection
- 50mA to 3.15A Programmable Input Current Limit
- 50mA to 3.2A Programmable Constant Current Charge
- Remote Differential Voltage Sensing
- 600kHz or 1.2MHz Switching Frequency Options
- System Instant On with Smart Power Selector Power-Path
- Charge Safety Timer
- Die Temperature Regulation with Thermal Foldback
  Loop
- Input Power Management with Adaptive Input Current Limit (AICL) and Input Voltage Regulation
- $10m\Omega$  BATT to SYS Switch, Up to 10A Overcurrent Threshold
- Reverse Buck Mode 5.1V/1.5A to Support USB OTG
- JEITA Compliant with NTC Thermistor Monitor
- I<sup>2</sup>C or Resistor Programmable
- 3.458mm x 3.458mm 49-Bump WLP

Ordering Information appears at end of data sheet.

### **Applications**

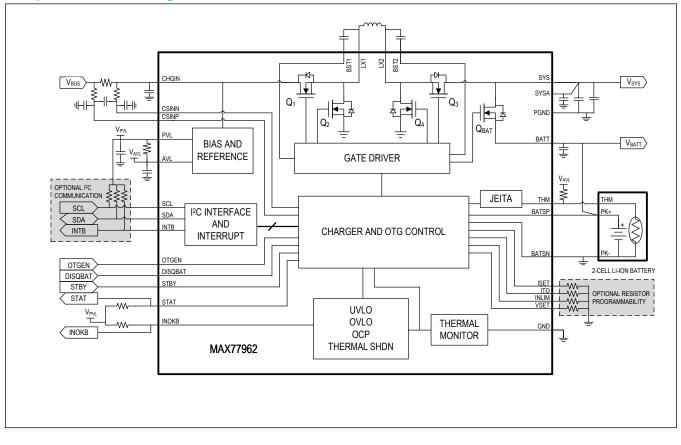

- USB Type-C Powered Wide-Input Charging Applications
- 2-Cell Battery Powered Devices

### **Absolute Maximum Ratings**

CHGIN to GND	0.3V to +30.0V
CSINP, CSINN to CHGIN	0.3V to +0.3V
LX1 to PGND	0.3V to +30.0V
LX2 to PGND	0.3V to +16.0V
BST1 to PVL	0.3V to +30.0V
BST2 to PVL	0.3V to +16.0V
BST_ to LX	0.3V to +2.2V
SYS, SYSA to GND	0.3V to +12.0V
BATT to GND	0.3V to +12.0V
SYS to BATT	0.3V to +12.0V
BATSP to GND	0.3V to BATT + 0.3V
BATSN, PGND to GND	0.3V to +0.3V
PVL, AVL, ISET, VSET, INLIM, ITO, TH	M to GND-0.3V to +2.2V

AVL to PVL0.3V to +0.3V
DISQBAT, OTGEN, STBY, STAT, INOKB, INTB, SDA, SCL to
GND0.3V to +6.0V
CHGIN Continuous Current 6.5A <sub>RMS</sub>
LX1, PGND Continuous Current 6.5A <sub>RMS</sub>
LX2 Continuous Current 5.2A <sub>RMS</sub>
SYS Continuous Current 8.7A <sub>RMS</sub>
BATT Continuous Current 5.2A <sub>RMS</sub>
Continuous Power Dissipation (Multilayer Board) ( $T_A = +70^{\circ}C$ ,
derate 35.7mW/°C above +70°C)
Operating Temperature Range40°C to +85°C
Storage Temperature Range65°C to +150°C

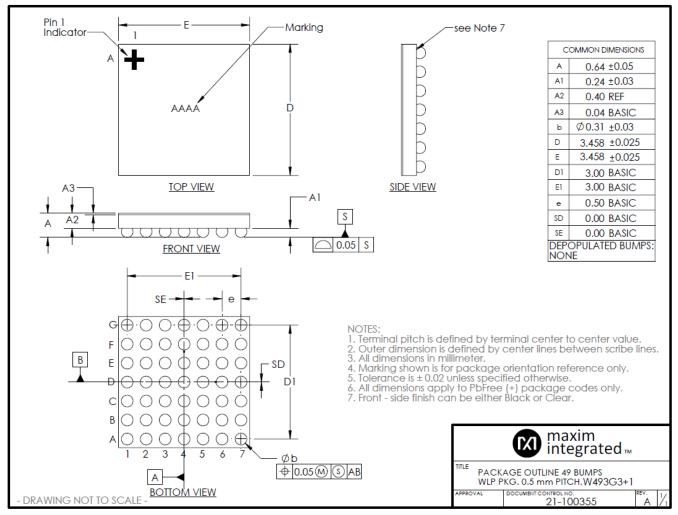

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### **Package Information**

#### 49-Bump WLP

Package Code	W493G3+1
Outline Number	<u>21-100355</u>
Land Pattern Number	Refer to Application Note 1891
Thermal Resistance, Four-Layer Board:	
Junction to Ambient ( $\theta_{JA}$ )	34.87°C/W

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

For the latest package outline information and land patterns (footprints), go to <u>www.maximintegrated.com/packages</u>. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to <u>www.maximintegrated.com/thermal-tutorial</u>.

### **Electrical Characteristics (continued)**

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
SYS, SYSA Leakage		$V_{SYS} = V_{SYSA} = 8.4V, V_{BATT} = 0V,$ Charger Disabled, $T_A = +25^{\circ}C$		0.01	10	μA
Current		$V_{SYS} = V_{SYSA} = 8.4V, V_{BATT} = 0V,$ Charger Disabled, $T_A = +85^{\circ}C$ (Note 1)		1		μΑ
CSINP, CSINN Leakage Current	ICSINP, ICSINN	$V_{CHGIN}$ = 23.7V, $V_{CSINP}$ = $V_{CSINN}$ = 23.7V, $T_A$ = +25°C	-1		+1	μA
SWITCH MODE CHARGI	ER / SMART PO	VER SELECTOR				
BATT to SYS Dropout Resistance	R <sub>BAT2SYS</sub>			10	17	mΩ
BATT to SYS Reverse Regulation Voltage	V <sub>BSREG</sub>			90		mV
SWITCH MODE CHARGI	ER / BATT TO SY	S OVERCURRENT ALERT				
Battery Overcurrent Threshold Range	IBOVCR	Programmable from 3A to 10A; option to disable	3		10	A
Battery Overcurrent Debounce Time	t <sub>BOVRC</sub>	Response time for generating the overcurrent interrupt (Note 3)			3.3	ms
SWITCH MODE CHARG	ER / THERMAL F	OLDBACK				
Junction Temperature Thermal Regulation Loop Setpoint Program Range	TREG	Junction temperature when charge current is reduced; programmable from 85°C to 130°C in 5°C steps; default value is 115°C	85		130	°C
Thermal Regulation Gain	A <sub>TJREG</sub>	The charge current is decreased 5% of the fast-charge current setting for every degree that the junction temperature exceeds the thermal regulation temperature. This slope ensures that the full-scale current of 3.2A is reduced to 0A by the time the junction temperature is 20°C above the programmed loop set point. For lower programmed charge currents such as 480mA, this slope is valid for charge current reductions down to 80mA; below 100mA the slope becomes shallower but the charge current still reduced to 0A if the junction temperature is 20°C above the programmed loop set point. (Note 1)		-5		%/°C
SWITCH MODE CHARG	ER / THERMISTO	OR MONITOR

### **Bump Configuration**

### MAX77962

### **Bump Descriptions**

PIN	NAME	FUNCTION
A1	BST1	High-Side Input MOSFET Driver Supply. Bypass BST1 to LX1 with a 0.22µF/6.3V capacitor.
B1, B2, B3, B4	CHGIN	Buck-Boost Charger Input. CHGIN is also the buck output when the charger is operating in the reverse mode. Bypass with two $10\mu$ F/35V ceramic capacitors from CHGIN to PGND.
C1, C2, C3, C4	LX1	Inductor Connection One. Connect an inductor between LX1 and LX2.
D1, D2, D3, D4	PGND	Power Ground for Buck-Boost Low-Side MOSFETs
E1, E2, E3	LX2	Inductor Connection Two. Connect an inductor between LX1 and LX2.
E4, F1, F2, F3, F4	SYS	System Supply Output. Bypass SYS to PGND with two 22µF/16V ceramic capacitors.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

# **Bump Descriptions (continued)**

PIN	NAME	FUNCTION
G3	OTGEN	Active-High Input. Connecting the OTGEN pin to high enables the OTG function. When the OTGEN pin is pulled low, the OTG enable function is controlled by the I <sup>2</sup> C interface. Before enabling the OTG function, disable skip mode with DISKIP = 1. To pull the OTGEN pin low with a pulldown resistor, the resistance must be lower than $44k\Omega$ .
G2	DISQBAT	Active-High Input. Connect high to disable the integrated $Q_{BAT}$ FET between SYS and BATT. Charging is disabled when DISQBAT connects to high. When DISQBAT is pulled low, $Q_{BAT}$ FET control is defined in <u>Table 1</u> . To pull the DISQBAT pin low with a pulldown resistor, the resistance must be lower than 44k $\Omega$ .
G1	BST2	High-Side Output MOSFET Driver Supply. Bypass BST2 to LX2 with a $0.22\mu$ F/6.3V capacitor.
G4	BATSN	Battery Voltage Differential Sense Negative Input. Connect to the negative terminal of the battery pack.
D5	BATSP	Battery Voltage Differential Sense Positive Input. Connect to the positive terminal of the battery pack.
E5, F5, G5	BATT	Battery Power Connection. Connect to the positive terminal of the battery pack. Bypass BATT to PGND with a $10\mu$ F/16V capacitor. All BATT pins must be connected together externally.
G6	ТНМ	Thermistor Input. Connect a negative temperature coefficient (NTC) thermistor from THM to GND. Connect a resistor equal to the thermistor +25°C resistance from THM to AVL. JEITA controlled charging available with JEITA_EN = 1. Charging is suspended when the thermistor voltage is outside of the hot and cold limits. Connect THM to GND to disable the thermistor temperature sensor. Connect THM to AVL to emulate battery removal and prevent charging.
G7	SCL	Serial Interface I <sup>2</sup> C Clock Input
F7	SDA	Serial Interface I <sup>2</sup> C Data. Open-drain output.
F6	STAT	Charger Status Output. Active-low, open-drain output, connect to the pullup rail through a 200kΩ resistor. Pulls low when the charging is in progress. Otherwise, STAT is high impedance. STAT toggles between low and high (when connected to a pullup rail) during charge. STAT becomes low when top-off threshold is detected and charger enters done state. STAT becomes high (when connected to a pullup rail) when charge faults are detected.
E7	INOKB	Input Power-OK/OTG Power-OK Output. Active-low, open-drain output pulls low when the CHGIN voltage is valid.
D7	INTB	Active-Low, Open-Drain Interrupt Output. Connect a pullup resistor to the pullup power source.
E6	SYSA	SYS voltage sensing input for SYS UVLO and OVLO detection.
C5, C6, C7, D6	GND	Analog Ground
B7	INLIM	Charger Input Current Limit Setting Input. Connect a resistor (R <sub>INLIM</sub> ) from INLIM to GND programs the charger input current limit. See <u>Table 4</u> .
B6	ISET	Fast-Charge Current Setting Input. Connecting a resistor ( $R_{ISET}$ ) from ISET to GND programs the fast-charge current. See <u>Table 5</u> .
A7	VSET	Charge Termination Voltage Setting Input. Connecting a resistor ( $R_{VSET}$ ) from VSET to GND programs the charge termination voltage. See <u>Table 7</u> .
A6	ΙΤΟ	Top-Off Current Setting Input. Connecting a resistor (R <sub>ITO</sub> ) from ITO to GND programs the top-off current. See <u>Table 6</u> .
A5	AVL	Analog Voltage Supply for On-Chip, Low-Noise Circuits. Bypass with a $4.7\mu$ F/6.3V ceramic capacitor to GND and connect AVL to PVL with a $4.7\Omega$ resistor.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

# **Bump Descriptions (continued)**

PIN	NAME	FUNCTION
A4	PVL	Internal Bias Regulator High Current Output Bypass Pin. Supports internal noisy and high current gate drive loads. Bypass to GND with a minimum $4.7\mu$ F/6.3V ceramic capacitor, and connect AVL to PVL with a $4.7\Omega$ resistor. Powering external loads from PVL is not recommended, other than pullup resistors.
B5	STBY	Active-High Input. Connect high to disable the DC-DC between CHGIN input and SYS output. Battery supplies the system power if the $Q_{BAT}$ is on. See <u>Table 1</u> . Connect low to control the DC-DC with the power-path state machine. To pull the STBY pin low with a pulldown resistor, the resistance must be lower than $44k\Omega$ .
A3	CSINP	Input Current Sense Positive Input
A2	CSINN	Input Current Sense Negative Input

### **Detailed Description**

### **Charger Configuration**

The MAX77962 is a highly-flexible, highly-integrated switch mode charger. Autonomous charging inputs configure the charger without host  $I^2C$  interface. See the <u>Autonomous Charging</u> section for more details. The IC has an  $I^2C$  interface which allows the host controller to program and monitor the charger. Charger configuration registers, interrupt, interrupt mask, and status registers are described in the <u>Register Map</u>.

### CHGIN Standy Input (STBY)

The host can reduce the ICs CHGIN supply current by driving the STBY pin to high or setting the STBY\_EN bit to '1'. When STBY is pulled high or STBY\_EN bit is set to '1', the DC-DC turns off. When STBY is pulled low and STBY\_EN bit is set to '0', the DC-DC is controlled by the power-path state machine. To pull the STBY pin low with a pulldown resistor, the resistance must be lower than  $44k\Omega$ .

### Battery to SYS Q<sub>BAT</sub> Disable Input (DISQBAT)

The host can disable the  $Q_{BAT}$  switch by setting the DISIBS bit to 1 or driving the DISQBAT pin to high. Charging stops when the  $Q_{BAT}$  switch is disabled.

When DISQBAT is pulled low and DISIBS bit is set to 0,  $Q_{BAT}$  FET control is defined in <u>Table 1</u>. To pull the DISQBAT pin low with a pulldown resistor, the resistance must be lower than 44k $\Omega$ .

### **QBAT** and DC-DC Control—Configuration Table

The  $Q_{BAT}$  control and the DC-DC control depend on both hardware pins (OTGEN, DISQBAT and STBY) and their associated I<sup>2</sup>C registers.

### Table 1. QBAT and DC-DC Control Configuration Table

OTGEN (PIN) OR MODE [3:0] = 0xA (I <sup>2</sup> C)	DISQBAT (PIN)	DISIBS (I <sup>2</sup> C)	STBY (PIN)	STBY_EN (I <sup>2</sup> C)	CHGIN	Q <sub>BAT</sub>	DC-DC
			Low	0	x	Power-Path State Machine/Internal Logic Control	Power-Path State Machine/Internal Logic Control
				1	х	Enable	
0	Low	0	Valid (SYS is powered from battery through Q <sub>BAT</sub> switch while DC-DC is disabled)		Disable

1	x	x	x	x	x	Enable (if not in factory ship mode)	Power-Path State Machine/Internal Logic Control (if not in factory ship mode)

### Table 1. QBAT and DC-DC Control Configuration Table (continued)

### **Thermistor Input (THM)**

The thermistor input can be utilized to achieve functions including, charge suspension, JEITA compliant charging, and battery removal detection. The thermistor monitoring feature can be disabled by connecting the THM pin to ground.

#### Charge Suspension

The THM input connects to an external negative temperature coefficient (NTC) thermistor to monitor battery or system temperature. Charging stops when the thermistor temperature is out of range (T < T<sub>COLD</sub> or T > T<sub>HOT</sub>). The charge timers are reset. The CHG\_DTLS[3:0] and CHG\_OK register bits report the charging suspension status, and the CHG\_I interrupt bit is set. When the thermistor comes back into range (T<sub>COLD</sub> < T < T<sub>HOT</sub>), charging resumes and the charge timer restarts.

### JEITA Compliant Charging

JEITA compliant charging is available with JEITA\_EN = 1. See the <u>JEITA Compliance</u> section for more details.

#### Battery Removal Detection

Connecting THM to AVL emulates battery removal and prevents charging.

#### **Disable Thermistor Monitoring**

Connecting THM to GND disables the thermistor monitoring function, and JEITA controlled charging is unavailable in this configuration. The IC detects an always connected battery when THM is grounded, and charging starts automatically when a valid adapter is plugged in. In applications with removable batteries, do not connect THM to GND because the IC cannot detect battery removal when THM is grounded. Instead, connecting THM to the thermistor pin in the battery pack is recommended.

Since the thermistor monitoring circuit employs an external bias resistor from THM to AVL, the thermistor is not limited only to  $10k\Omega$  (at +25°C). Any resistance thermistor can be used as long as the value is equivalent to the thermistors +25°C resistance. For example, with a  $10k\Omega$  at R<sub>TB</sub> resistor, the charger enters a temperature suspend state when the thermistor resistance falls below  $3.97k\Omega$  (too hot) or rises above  $28.7k\Omega$  (too cold). This corresponds to a 0°C to +50°C range when using a  $10k\Omega$  NTC thermistor with a beta of 3500. The general relation of thermistor resistance to temperature is defined by the following equation:

$$R_T = R_{25} x e^{\{\beta x (\frac{1}{T + 273^{\circ}C} - \frac{1}{298^{\circ}C})\}}$$

where:

 $R_T$  = The resistance in  $\Omega$  of the thermistor at temperature T in Celsius.

 $R_{25}$ = The resistance in  $\Omega$  of the thermistor at +25°C.

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

 $\beta$  = The material constant of the thermistor, which typically ranges from 3000k to 5000k.

T = The temperature of the thermistor in  $^{\circ}$ C.

Some designs might prefer other thermistor temperature limits. Threshold adjustment can be accommodated by changing  $R_{TB}$ , connecting a resistor in series and/or in parallel with the thermistor, or using a thermistor with different  $\beta$ . For example, a +45°C hot threshold and 0°C cold threshold can be realized by using a thermistor with a  $\beta$  to 4250 and connecting 120k $\Omega$  in parallel. Since the thermistor resistance near 0°C is much higher than it is near +50°C, a large parallel resistance lowers the cold threshold, while only slightly lowering the hot threshold. Conversely, a small series resistance raises the cold threshold, while only slightly raising the hot threshold. Raising  $R_{TB}$  raises both the hot and cold threshold, while lowering  $R_{TB}$  lowers both thresholds.

Since AVL is active whenever a valid input power is connected at DC, thermistor bias current flows at all times, even when charging is disabled. When using a  $10k\Omega$  thermistor and a  $10k\Omega$  pullup to ADCREF, this results in an additional 250µA load. This load can be reduced to  $25\mu$ A by instead using a  $100k\Omega$  thermistor and  $100k\Omega$  pullup resistor.

		THERMISTO	DR		TRIP TEMPERATURES				
R <sub>25</sub> (Ω)	β	R <sub>TB</sub> (Ω)	R <sub>15</sub> (Ω)	R <sub>45</sub> (Ω)	T <sub>COLD</sub> (°C)	T <sub>COOL</sub> (°C)	T <sub>WARM</sub> (°C)	T <sub>HOT</sub> (°C)

### Table 2. Trip Temperatures for Different Thermistors

### Autonomous Charging

The MAX77962 supports autonomous charging without  $I^2C$ . In applications without  $I^2C$ -serial communication, use the following pins to configure the IC charger:

INLIM, ITO, ISET, VSET, OTGEN, DISQBAT, and STBY.

INLIM, ITO, ISET, and VSET pins are used to program the charger's input current limit, top-off current, constant-charging current, and termination voltage.

Connect a valid resistor from each of these pins to ground to program the charger. See the <u>Pin Descriptions</u> of each pin for details.

Connect all four pins (INLIM, ITO, ISET, VSET) to PVL to use the default values for the associated charger registers.

For autonomous charging, it is considered an abnormal condition if some of these pins (INLIM, ITO, ISET, VSET) connect to a valid resistor but others do not (for example, open or connects to PVL or connects to a resistor that is out of range). When this happens, the MAX77962 allows the DC-DC to switch and regulate the SYS voltage, but disables charging for safety reasons. The STAT pin reports no charge.

### Table 3. INLIM, ITO, ISET, and VSET Pin Connections for Autonomous Charging

INLIM PIN	ITO PIN	ISET PIN	VSET PIN	AUTONOMOUS CHARGING
Valid resistor	Valid resistor	Valid resistor	Valid resistor	Normal, charger configuration is programmed by resistors
Tied to PVL	Tied to PVL	Tied to PVL	Tied to PVL	Normal, charger configuration uses default values
All other connections				Abnormal, no charging

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### Charger Input Current Limit Setting Input (INLIM)

When a valid charge source is applied to CHGIN, the IC limits the current drawn from the charge source to the value programmed with INLIM pin.

The default charger input current limit is programmed with the resistance from INLIM to GND. See Table 4.

If  $I^2C$  is used in the application, the CHGIN input current limit can also be reprogrammed with CHGIN\_ILIM[6:0] register bits after the device powers up. Connect the INLIM pin to PVL to use  $I^2C$  default settings.

### Table 4. INLIM Program Options Lookup Table

R <sub>INLIM</sub> (Ω)	CHGIN INPUT CURRENT LIMIT (mA) DEFAULT VALUE OF CHGIN_ILIM[6:0]	
Tied to PVL	500	
226000	100	
178000	200	
140000	300	
110000	400	
86600	500	
69800	1000	
54900	1500	
39200	2000	
22600	2500	
17800	3000	

#### Fast-Charge Current Setting Input (ISET)

When a valid input source is present, the battery charger attempts to charge the battery with a fast-charge current programmed with the ISET pin.

The default fast-charge current is programmed with the resistance from ISET to GND. See <u>Table 5</u>.

If  $I^2C$  is used in the application, the fast-charge current can also be reprogrammed with CHGCC[8:0] register bits after the device powers up. Connect the ISET pin to PVL to use  $I^2C$  default settings.

### Table 5. ISET Program Options Lookup Table

R <sub>ISET</sub> (Ω)	FAST-CHARGE CURRENT SELECTION (mA) DEFAULT VALUE OF CHGCC[8:0]	
Tied to PVL	450	
226000	100	
178000	200	
140000	300

22600	2500	
17800	3000	

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### **Top-Off Current Setting Input (ITO)**

When the battery charger is in the top-off state, the top-off charge current is programmed by ITO pin.

The default top-off charge current is programmed with the resistance from ITO to GND. See Table 6.

If  $I^2C$  is used in the application, the top-off current can also be reprogrammed with TO\_ITH[2:0] register bits after the device powers up. Connect ITO pin to PVL to use  $I^2C$  default settings.

### Table 6. ITO Program Options Lookup Table

R <sub>ITO</sub> (Ω)	TOP-OFF CURRENT THRESHOLD (mA) DEFAULT VALUE OF TO_ITH[2:0]
Tied to PVL	25
226000	25
178000	50
140000	75
110000	100
86600	125
69800	150

#### Charge Termination Voltage Setting Input (VSET)

The default charge termination voltage is programmed with the resistance from VSET to GND. See Table 7.

If  $I^2C$  is used in the application, the charge termination voltage can also be reprogrammed with CHG\_CV\_PRM[6:0] register bits after the device powers up. Connect the VSET pin to PVL to use  $I^2C$  default settings.

### Table 7. VSET Program Options Lookup Table

R <sub>VSET</sub> (Ω)	CHARGE TERMINATION VOLTAGE SETTING (V) DEFAULT VALUE OF CHG_CV_PRM[6:0]
Tied to PVL	8.10
226000	8.10
178000	8.16
140000	8.22

5490	8.86

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### Switch Mode Charger

The IC features a switch mode buck-boost charger for a two-cell lithium ion (Li+) or lithium polymer (Li-polymer) battery. The charger operates with a wide input range from 3.5V to 23V, which is ideal for USB-C charging applications. The charger input current limit is programmable from 50mA to 3.15A, which is flexible to operate from either an AC-to-DC wall charger or a USB-C adapter.

The IC offers a high level of integration and does not require any external MOSFETs to operate, which significantly reduces the solution size. It operates with a switching frequency of 600kHz or 1.2MHz, which is ideal for portable devices that benefit from small solution size and high-efficiency. The battery charging current is programmable from 50mA to 3.2A, which accommodates small or large capacity batteries.

When the input source is not available, the IC can be enabled in a reverse-buck mode, delivering energy from the battery to the input, CHGIN, commonly known as USB On-the-Go (OTG). In OTG mode, the regulated CHGIN voltage is 5.1V with programmable current limit up to 1.5A.

Maxim's Smart Power Selector architecture makes the best use of the limited adapter power and the battery power to power the system. Adapter power that is not used for the system charges the battery. When system load exceeds the input limit, the battery provides additional current to the system up to the BAT to SYS overcurrent threshold, programmable with B2SOVRC[3:0] I<sup>2</sup>C register bits. All power switches for charging and switching the system load between battery and adapter power are integrated on chip—no external MOSFETs required.

Maxim's proprietary process technology allows for low- $R_{DSON}$  devices in a small solution size. The resistance between BAT to SYS is 10m $\Omega$  (typ), allowing low power dissipation and long battery life.

A multitude of safety features ensure reliable charging. Features include charge timers, watchdog, junction thermal regulation, and over-/under- voltage protection.

#### Smart Power Selector (SPS)

The SPS architecture includes a network of internal switches and control loops that efficiently distributes energy between an external power source (CHGIN), the battery (BAT) and the system (SYS). This architecture allows power-path operation with system instant on with a dead battery.

The Simplified Block Diagram shows the Smart Power Selector switches and gives them the following names:  $Q_{1,} Q_{2,} Q_{3}$ ,  $Q_{4}$  and  $Q_{BAT}$ .

#### Power Switches and Current Sense Resistor Descriptions

- CHGIN Current Sense Resistor: As shown in the Simplified Block Diagram, the CHGIN current is monitored with the input current sensing resistor, R<sub>S1</sub>, connected between CSINP and CSINN pins.
- DC-DC Switches: Q<sub>1</sub>, Q<sub>2</sub>, Q<sub>3</sub>, and Q<sub>4</sub> are the DC-DC switches which can operate as a buck (step-down) or a boost (step-up) depends on the external power source and battery voltage conditions.
- Battery-to-System Switch: Q<sub>BAT</sub> is used to control battery charging and discharging operations.

#### I<sup>2</sup>C Configuration Register Bits

- MODE[3:0] configures the Smart Power Selector mode to be charging, OTG, or DC-DC mode respectively. See the MODE[3:0] register bit description in the <u>Register Map</u> for details.
- VCHGIN\_REG[4:0] sets the CHGIN regulation voltage, when the IC operates in forward mode (CHGIN has a valid power source). See the <u>CHGIN Regulation Voltage</u> section for details.
- MINVSYS[2:0] sets the minimum system regulation voltage. See the <u>SYS Regulation Voltage</u> section for details.
- B2SOVRC[3:0] sets the battery to system discharge over-current alert threshold.

#### **Energy Distribution Priority**

- With a valid external power source at CHGIN:
  - The external power source is the primary source of energy.
  - The battery is the secondary source of energy.
  - Energy delivery to SYS has the highest priority.
  - Any remaining energy from the power source that is not required by the system is available to the battery charger.

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

- With no valid external power source at CHGIN:
  - The battery is the primary source of energy.
  - When OTG mode is enabled, energy delivery to SYS has the highest priority.
  - Any remaining energy from the battery that is not required by the system is available to power the CHGIN.

#### CHGIN Regulation Voltage

- In forward mode (when CHGIN is powered from a valid external source), CHGIN voltage is regulated to VCHGIN\_REG[4:0] when a high impedance or current limited source is applied. VCHGIN might experience significant voltage droop from the high impedance source when the IC extracts high power from the source. Regulating VCHGIN allows the IC to extract the most power from the power source. See the <u>Adaptive Input Current Limit (AICL) and Input</u> <u>Voltage Regulation</u> section for more details.
- In reverse mode (OTG), CHGIN voltage is regulated to 5.1V with programmable current limit up to 1.5A (OTG\_ILIM[2:0]).

#### **SYS Regulation Voltage**

With a valid external power source at CHGIN:

- When the DC-DC is enabled and the charger is disabled, MODE[3:0] = 0x04, V<sub>SYS</sub> is regulated to V<sub>BATTREG</sub> (CHG\_CV\_PRM), and Q<sub>BAT</sub> is off.
- When the DC-DC is enabled and the charger is enabled, MODE[3:0] = 0x05, but in a non-charging state such as Done, Thermistor Suspend, Watchdog Suspend, or Timer Fault, V<sub>SYS</sub> is regulated to V<sub>BATTREG</sub> (CHG\_CV\_PRM) and Q<sub>BAT</sub> is off.
- When the DC-DC is enabled and the charger is enabled, MODE[3:0] = 0x05, and in a valid charging state such as Precharge, Trickle Charge, Fast-Charge (CC or CV), or Top-Off, V<sub>SYS</sub> is regulated to V<sub>SYSMIN</sub> when V<sub>BATT</sub> < V<sub>SYSMIN</sub> 500mV; the charger operates as a linear regulator and the power dissipation can be calculated with [P = (V<sub>SYSMIN</sub> V<sub>BATT</sub>) x I<sub>BATT</sub>]. Otherwise, the Q<sub>BAT</sub> switch is fully closed when V<sub>BATT</sub> > V<sub>SYSMIN</sub> 500mV, and V<sub>SYS</sub> = V<sub>BATT</sub> + I<sub>BATT</sub> x R<sub>BAT2SYS</sub>.
- In all the modes described previously, when the power demand on SYS exceeds the input source power limit, and V<sub>SYS</sub> drops to V<sub>BATT</sub> - V<sub>BSREG</sub>, the battery automatically provides supplemental power to the system.

Without a valid external power source at CHGIN and with OTG mode enabled, MODE[3:0] = 0xA:

• The  $Q_{BAT}$  switch is closed and  $V_{SYS}$  =  $V_{BATT}$  -  $I_{BATT}$  x  $R_{BAT2SYS}$ 

#### **Power States**

The IC transitions between power states as input/battery and load conditions dictate.

The IC provides four (4) power states and one (1) no power state. Under power limited conditions, the power-path feature maintains SYS and USB-OTG loads at the expense of the battery charge current. In addition, the battery supplements the input power when required. See the <u>Smart Power Selector (SPS)</u> section for more details. As shown, transitions between power states are initiated by detection/removal of valid power sources, OTG events, and under-voltage conditions.

1. NO INPUT POWER, <u>MODE[3:0] = undefined</u>: No input adapter or battery is detected. The charger and system are off. Battery is disconnected.

2. BATTERY-ONLY, <u>MODE[3:0] = any mode</u>: CHGIN is invalid or outside the input voltage operating range. Battery is connected to power the SYS load (Q<sub>BAT</sub> = on).

3. NO CHARGE—DC-DC in FORWARD mode,  $\underline{MODE[3:0]} = 0x04$ : CHGIN input is valid, DC-DC supplies power to SYS. DC-DC operates from a valid input. Battery is disconnected ( $Q_{BAT} = OFF$ ) when SYS load is less than the power that DC-DC can supply.

4. CHARGE—DC-DC in FORWARD mode, <u>MODE[3:0] = 0x05</u>: CHGIN input is valid, DC-DC supplies power to SYS and charges the battery with I<sub>BATT</sub>. DC-DC operates from a valid input.

5. OTG—DC-DC in REVERSE mode (OTG), <u>MODE[3:0] = 0x0A</u>: OTG is active. Battery is connected to support SYS and OTG loads ( $Q_{BAT}$  = on), and charger operates in REVERSE buck mode.

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### Powering Up with Charger Disabled by Default

The MAX77962's default power state is CHARGE - DC-DC in FORWARD mode, MODE[3:0] = 0x05. For battery authentication/safety purposes, the MAX77962 can be configured to keep charging disabled, while allowing the DC-DC to switch and regulate the SYS voltage, when power is applied to CHGIN. To implement this and enable the charger when appropriate:

- Connect at least one of the INLIM, ITO, ISET or VSET pins to a valid resistor while tying the others (at least one) to PVL. CHG\_DTLS = 0x05 and CHG\_OK = 0.
- The system processor can configure the charger using the I<sup>2</sup>C interface.
- The system processor enables charging by setting COMM\_MODE to 1 (default is 0).

See the <u>Wide-Input I<sup>2</sup>C Programmable Charger with Charger Disabled</u> diagram for a pin connection example. INLIM is connected to a valid resistor while ITO, ISET, and VSET tie to PVL. The default input current limit is programmed by R<sub>INLIM</sub>, while the default top-off current, constant charging current, and termination voltage use their default value. The system processor can re-program all four settings using the I<sup>2</sup>C interface if needed.

#### Input Validation

The charger input is compared with several voltage thresholds to determine if it is valid. A charger input must meet the following characteristics to be valid:

- CHGIN must be above V<sub>CHGIN\_UVLO</sub> to be valid. Once CHGIN is above UVLO threshold, the information is latched and can only be reset when charger is in adaptive input current loop (AICL) and input current is lower than IULO threshold of 30mA.
- CHGIN must be below its overvoltage-lockout threshold (V<sub>CHGIN OVLO</sub>).

The device generates a CHGIN\_I interrupt (maskable with CHGIN\_M bit) when CHGIN status changes. Read the CHGIN input status with CHGIN\_OK and CHGIN\_DTLS[1:0] register bits.

#### Adaptive Input Current Limit (AICL) and Input Voltage Regulation (CHGIN\_REG)

The IC features input power management to extract maximum input power while avoiding input source overload. The AICL and CHGIN\_REG features allow the charger to extract more energy from relatively high resistance charge sources with long cables, non-compliant USB hubs, or current limited adapters. In addition, the input power management allows the IC to perform well with adapters that have poor transient load responses.

With a high resistance source, the charger input voltage drops substantially when it draws large current from the source. The charger's input voltage regulation loop automatically reduces the current drawn from the input in order to regulate the input voltage at  $V_{CHGIN\_REG}$ . If the input current is reduced to  $I_{CHGIN\_REG\_OFF}$  (50mA typ) and the input voltage is still below  $V_{CHGIN\_REG}$ , the charger input turns off.  $V_{CHGIN\_REG}$  is programmable with VCHGIN\\_REG[4:0] register bits.

With a current limited source, if the ICs input current limit is programmed above the current limit of the adapter, the charger input voltage starts to drop when the input current drawn exceeds the source current limit. The charger's input voltage regulation loop allows the IC to reduce its input current and operate at the current limit of the adapter.

When operating with the input voltage regulation loop active, an AICL\_I interrupt is generated, AICL\_OK sets to 0. The device prioritizes system energy delivery over battery charging. See the <u>Smart Power Selector (SPS)</u> section for more details.

To extract the most input power from a current limited charge source, monitor the AICL\_OK status while decreasing the CHGIN\_ILIM[6:0] register setting. Lowering the CHGIN\_ILIM[6:0] to a value below the current limit of the adapter causes the input voltage to rise. Although the CHGIN\_ILIM[6:0] is lowered, more power can be extracted from the adapter when the input voltage rises.

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### Input Self-Discharge

To ensure that a rapid removal and reinsertion of a charge source always results in a charger input interrupt, the charger input presents loading to the input capacitor to ensure that when the charge source is removed, the input voltage decays below the UVLO threshold in a reasonable time ( $t_{INSD}$ ). The input self-discharge is implemented with a 44k $\Omega$  resistor ( $R_{INSD}$ ) from CHGIN input to ground.

#### System Self-Discharge with No Power

To ensure a timely, complete, repeatable, and reliable reset behavior when the system has no power, the IC actively discharges the BATT and SYS nodes when the adapter is missing, the battery is removed, and  $V_{SYS}$  is less than  $V_{SYSUVLO}$ . The BATT and SYS discharge resistors are both 600 $\Omega$ .

#### **Charger States**

The IC utilizes several charging states to safely and quickly charge batteries as shown in Figure 1 and Figure 2. Figure 1 shows an exaggerated view of a Li+/Li-Poly battery progressing through the following charge states when there is no system load and the die and battery are close to room temperature: Prequalification  $\rightarrow$  Fast-charge  $\rightarrow$  Top-off  $\rightarrow$  Done.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

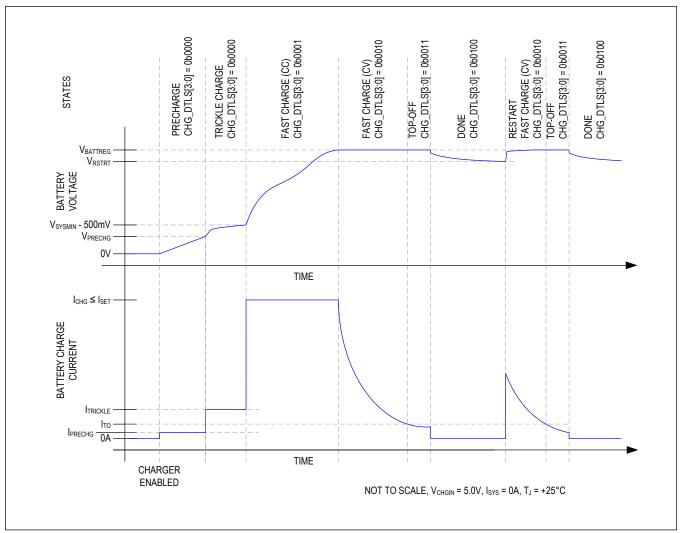

Figure 1. Li Battery Charge Profile

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

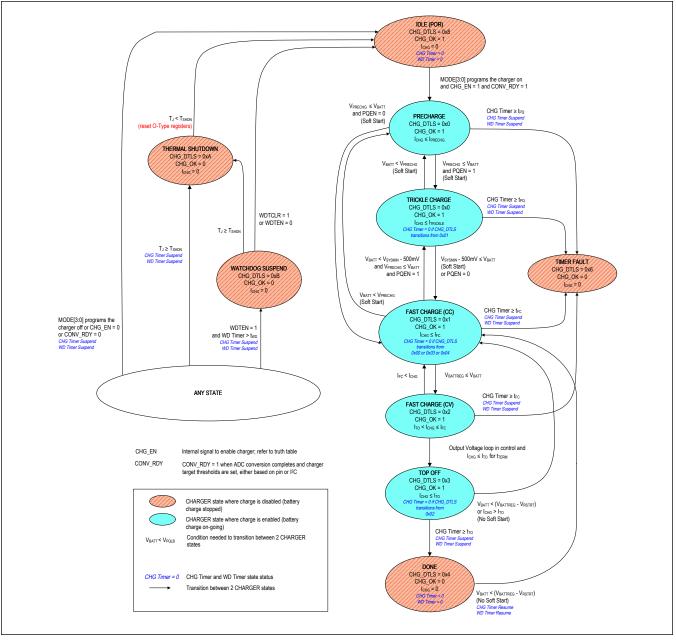

Figure 2. Charger State Diagram

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### No Input Power or Charger-Disabled Idle State

From any state shown in <u>Figure 2</u>, except thermal shutdown, the "no input power or charger disabled" state is entered whenever the charger is programmed to be off or the charger input CHGIN is invalid. After being in this state for t<sub>SCIDG</sub>, CHG\_DTLS is set to 0x08 and CHG\_OK is set to 1. A CHG\_I interrupt is generated if CHG\_OK was 0 previously.

While in the "no input power or charger disabled" state, the charger current is 0mA, the watchdog and charge timers are forced to 0, and the power to the system is provided by either the battery or the adapter. When both battery and adapter power are available, the adapter provides primary power to the system and the battery contributes supplemental energy to the system if necessary.

To exit the "no input power or charger disabled" state, the charger input must be valid and the charger has to be enabled.

#### **Precharge State**

As shown in <u>Figure 2</u>, the charger enters the precharge state when the battery voltage is less than V<sub>PRECHG</sub>. After being in this state for t<sub>SCIDG</sub>, a CHG\_I interrupt is generated if CHG\_OK was 0 previously, CHG\_OK is set to 1, and CHG\_DTLS is set to 0x00. In the precharge state, charge current into the battery is I<sub>PRECHG</sub>.

The following events cause the state machine to exit this state:

- Battery voltage rises above V<sub>PRECHG</sub> and the charger enters the next state in the charging cycle: "Trickle Charge".
- If the battery charger remains in this state for longer than t<sub>PQ</sub>, the charger state machine transitions to the "Timer Fault" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

Note that the precharge state works with battery voltages down to 0V. The 0V operation typically allows this battery charger to recover batteries that have an "open" internal pack protector. Typically a battery pack's internal protection circuit opens if the battery has seen an overcurrent, undervoltage, or overvoltage. When a battery with an "open" internal pack protector is used with this charger, the precharge mode current flows into the 0V battery—this current raises the pack's terminal voltage to the level where the internal pack protection switch closes.

Note that a normal battery typically stays in the precharge state for several minutes or less. Therefore a battery that stays in the precharge for longer than  $t_{PQ}$  may be experiencing a problem.

#### Trickle Charge State

As shown in <u>Figure 2</u>, the charger state machine is in trickle charge state when  $V_{PRECHG} < V_{BATT} < V_{SYSMIN}$  - 500mV. After being in this state for t<sub>SCIDG</sub>, a CHG\_I interrupt is generated if CHG\_OK was 0 previously, CHG\_OK is set to 1, and CHG\_DTLS = 0x00.

With PQEN = 1(default) and the IC is in its trickle charge state, the current in the battery is less than or equal to ITRICKLE. When PQEN = 0, the charger skips the trickle charge state and transitions directly to the fast-charge state, and the battery charging current is less than or equal to  $I_{FC}$ .

Charge current may be less than ITRICKLE/I<sub>FC</sub> for any of the following reasons:

- The charger input is in input current limit.
- The charger input voltage is low.
- The charger is in thermal foldback.
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charge current.

Typical systems operate with PQEN = 1. When operating with PQEN = 0, the system's software usually sets  $I_{FC}$  to a low value such as 200mA and then monitors the battery voltage. When the battery exceeds a relatively low voltage such as 6V, then the system's software usually increases  $I_{FC}$ .

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

The following events cause the state machine to exit this state:

- When the battery voltage rises above V<sub>SYSMIN</sub> 500mV or the PQEN bit is cleared, the charger enters the next state in the charging cycle: "Fast-Charge (CC)".
- If the battery charger remains in this state for longer than t<sub>PQ</sub>, the charger state machine transitions to the "Timer Fault" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

Note that a normal battery typically stays in the trickle charge state for several minutes or less. Therefore a battery that stays in trickle charge for longer than  $t_{PQ}$  may be experiencing a problem.

#### Fast-Charge Constant Current (CC) State

As shown in <u>Figure 2</u>, the charger enters the fast-charge constant current (CC) state when  $V_{SYSMIN}$  - 500mV (typ) <  $V_{BATT} < V_{BATTREG}$ . After being in the fast-charge CC state for t<sub>SCIDG</sub>, a CHG\_I interrupt is generated if CHG\_OK was 0 previously, CHG\_OK is set to 1, and CHG\_DTLS = 0x01.

In the fast-charge CC state, the battery charging current is less than or equal to  $I_{FC}$ . Charge current may be less than  $I_{FC}$  for any of the following reasons:

- The charger input is in input current limit.
- The charger input voltage is low.
- The charger is in thermal foldback.
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charging current.

The following events cause the state machine to exit this state:

- When the battery voltage rises above V<sub>BATTREG</sub>, the charger enters the next state in the charging cycle: "Fast-Charge (CV)".
- If the battery charger remains in this state for longer than t<sub>FC</sub>, the charger state machine transitions to the "Timer Fault" state.
- If the watchdog timer is not serviced, the charger state machine transitions to the "Watchdog Suspend" state.

The battery charger dissipates the most power in the fast-charge constant current state, which causes the die temperature to rise. If the die temperature exceeds  $T_{REG}$ , the thermal foldback loop is engaged and  $I_{FC}$  is reduced. See the <u>Thermal Foldback</u> section for more information.

#### Fast-Charge Constant Voltage (CV) State

As shown in <u>Figure 2</u>, the charger enters the fast-charge constant voltage (CV) state when the battery voltage rises to  $V_{BATTREG}$  from the fast-charge CC state. After being in the fast-charge CV state for  $t_{SCIDG}$ , a CHG\_I interrupt is generated if CHG\_OK was 0 previously, CHG\_OK is set to 1, and CHG\_DTLS = 0x02.

In the fast-charge CV state, the battery charger maintains  $V_{BATTREG}$  across the battery and the charge current is less than or equal to  $I_{FC}$ . As shown in Figure 1, charger current decreases exponentially in this state as the battery becomes fully charged.

The Smart Power Selector control circuitry may reduce the charge current for any of the following reasons:

- The charger input is in input current limit.
- The charger input voltage is low.
- The charger is in thermal foldback.
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charge current.

The following events cause the state machine to exit this state:

- When the charger current is below ITO for tTERM, the charger enters the <u>Top-Off state</u>.
- If the battery charger remains in this state for longer than t<sub>FC</sub>, the charger state machine transitions to the <u>Timer Fault</u> <u>state</u>.
- If the watchdog timer is not serviced, the charger state machine transitions to the Watchdog Timer Suspend state.

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### **Top-Off State**

As shown in <u>Figure 2</u>, the top-off state can only be entered from the fast-charge CV state when the charger current decreases below  $I_{TO}$  for  $t_{TERM}$ . After being in the top-off state for  $t_{SCIDG}$ , a CHG\_I interrupt is generated if CHG\_OK was 0 previously, CHG\_OK is set to 1, and CHG\_DTLS = 0x03. In the top-off state the battery charger maintains  $V_{BATTREG}$  across the battery and typically the charge current is less than or equal to  $I_{TO}$ .

The Smart Power Selector control circuitry may reduce the charge current for any of the following reasons:

- The charger input is in input current limit.
- The charger input voltage is low.
- The charger is in thermal foldback.
- The system load is consuming adapter current. Note that the system load always gets priority over the battery charge current.

The following events cause the state machine to exit this state:

- After being in this state for the top-off time  $(t_{TO})$ , the charger enters the <u>Done state</u>.
- If V<sub>BATT</sub> < V<sub>BATTREG</sub> V<sub>RSTRT</sub>, the charger goes back to the <u>Fast-Charge (CC) state</u>.
- If the watchdog timer is not serviced, the charger state machine transitions to the Watchdog Timer Suspend state.

#### Done State

As shown in <u>Figure 2</u>, the battery charger enters its done state after the charger has been in the top-off state for  $t_{TO}$ . After being in this state for  $t_{SCIDG}$ , a CHG\_I interrupt is generated only if CHG\_OK was 0 previously, CHG\_OK is set to 0, and CHG\_DTLS = 0x04.

The following events cause the state machine to exit this state:

- If V<sub>BATT</sub> < V<sub>BATTREG</sub> V<sub>RSTRT</sub>, the charger goes back to the *Fast-Charge Constant Current state*.
- If the watchdog timer is not serviced, the charger state machine transitions to the <u>Watchdog Timer Suspend state</u>.

In the done state, the battery charging current ( $I_{CHG}$ ) is 0A and the charger presents a very low load ( $I_{MBDN}$ ) to the battery. If the system load presented to the battery is low (<<100µA), then a typical system can remain in the done state for many days. If left in the done state long enough, the battery voltage decays below the charging restart threshold ( $V_{RSTRT}$ ) and the charger state machine transitions back into the fast-charge CC state. There is no soft-start (di/dt limiting) during the done to fast-charge state transition.

#### Timer Fault State

The battery charger provides both a charge timer and a watchdog timer to ensure safe charging. As shown in Figure 2, the charge timer prevents the battery from charging indefinitely. The time that the charger is allowed to remain in its prequalification states is  $t_{PQ}$ . The time that the charger is allowed to remain in the fast-charge CC and CV states is  $t_{FC}$  which is programmable with FCHGTIME. Finally, the time that the charger is in the top-off state is  $t_{TO}$  which is programmable with TO\_TIME. Upon entering the timer fault state, a CHG\_I interrupt is generated without a delay, CHG\_OK is cleared, and CHG\_DTLS = 0x06.

The charger is off in the timer fault state. The charger can exit the timer fault state when the charger is programmed to be off then on again through the MODE bits or when DISQBAT pin is toggled from L-H-L. Alternatively, the charger input can be removed and re-inserted to exit the timer fault state (see the "ANY STATE" bubble in Figure 2).

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### Watchdog Timer Suspend State

The battery charger provides both a charge timer and a watchdog timer to ensure safe charging. As shown in Figure 2, the watchdog timer protects the battery from charging indefinitely in the event that the host hangs or otherwise cannot communicate correctly. The watchdog timer is disabled by default with WDTEN = 0. Enable the feature by setting WDTEN = 1. With watchdog timer enabled, the host controller must reset the watchdog timer within the timer period ( $t_{WD}$ ) in order for the charger to operate properly. Reset the watchdog timer by programming WDTCLR = 0x01.

If the watchdog timer expires, charging stops, a CHG\_I interrupt is generated if CHG\_OK was 1 previously, CHG\_OK is cleared, and CHG\_DTLS indicates that the charger is off because the watchdog timer expired. Once the watchdog timer expires, the charger may be restarted by programming WDTCLR = 0x01. The SYS node can be supported by the battery and/or the adapter through the DC-DC buck while the watchdog timer is expired.

#### Thermal Shutdown State

As shown in Figure 2, the state machine enters the thermal shutdown state when the junction temperature ( $T_J$ ) exceeds the device's thermal-shutdown threshold ( $T_{SHDN}$ ). When  $T_J$  is close to  $T_{SHDN}$ , the charger would have already folded back the input current to 0A (see the <u>Thermal Foldback</u> section for more details), so the charger and the DC-DC are effectively off. Upon entering this state, CHG\_I interrupt is generated if CHG\_OK was 1 previously, CHG\_OK is cleared, and CHG\_DTLS = 0x0A.

In the thermal shutdown state, the charger is off. MODE register (CHG\_CNFG\_00[3:0]) is reset to its default value as well as all O type registers.

#### **Thermal Management**

The IC charger uses several thermal management techniques to prevent excessive battery and die temperatures.

#### **Thermal Foldback**

Thermal foldback maximizes the battery charge current while regulating the IC junction temperature. As shown in Figure 3, when the die temperature exceeds the value programmed by REGTEMP ( $T_{REG}$ ), a thermal limiting circuit reduces the battery charger's target current by 5%/°C ( $A_{TJREG}$ ) with an analog control loop. When the charger transitions in and out of the thermal foldback loop, a CHG\_I interrupt is generated and the host microprocessor can read the status of the thermal regulation loop with the TREG status bit. Note that an active thermal foldback loop is not an abnormal operation and the thermal foldback loop status does not affect the CHG\_OK bit (only information contained within CHG\_DTLS affects CHG\_OK).

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

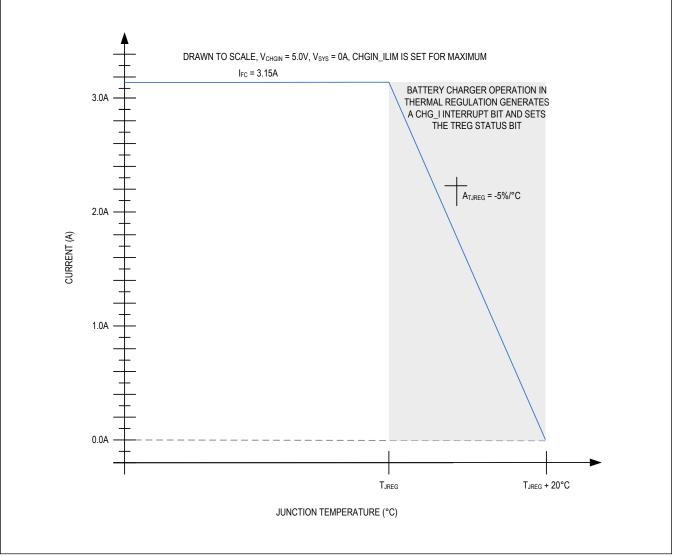

Figure 3. Charge Currents vs. Junction Temperature

#### **JEITA Compliance**

The IC safely charges Li+ batteries in accordance with JEITA specifications. The IC monitors the battery temperature with a NTC thermistor connected at the THM pin and automatically adjusts the fast-charge current and/or charge termination voltage as the battery temperature varies. JEITA controlled charging can be disabled by setting JEITA\_EN to 0. CHG\_DTLS and THM\_DTLS registers report JEITA controlled charging status.

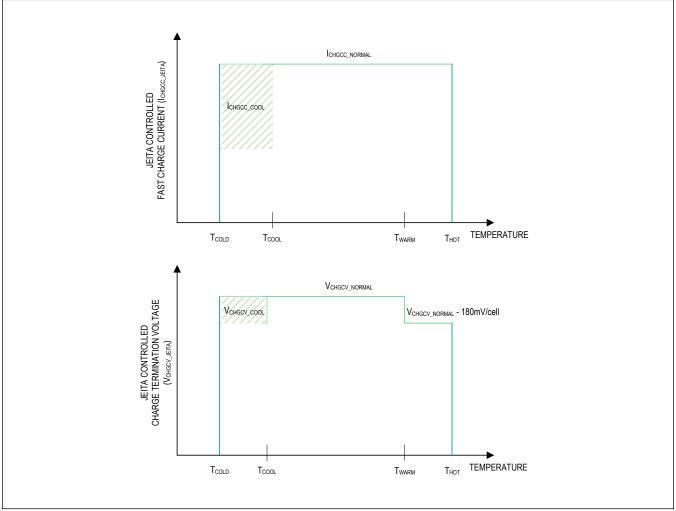

The JEITA controlled fast-charging current ( $I_{CHGCC\_JEITA}$ ) and charge termination voltage ( $V_{CHGCV\_JEITA}$ ) for  $T_{COLD} < T < T_{COOL}$  are programmable with I<sup>2</sup>C bits  $I_{CHGCC\_COOL}$  and  $V_{CHGCV\_COOL}$ .

The charge termination voltage for  $T_{WARM} < T < T_{HOT}$  is reduced to (CHG\_CV\_PRM - 180mV/cell), as shown in Figure <u>4</u>.

Charging is suspended when the battery temperature is too cold or too hot (T <  $T_{COLD}$  or  $T_{HOT}$  < T).

Temperature thresholds  $T_{COLD}$ ,  $T_{COOL}$ ,  $T_{WARM}$ , and  $T_{HOT}$  depend on the thermistor selection. See the <u>*Thermistor*</u> Input</u> section for more details.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

When battery charge current is reduced by 50%, the charger timer is doubled.

Figure 4. JEITA Compliance

#### **Thermal Shutdown**

The IC has a die temperature sensing circuit. When the die temperature exceeds the thermal-shutdown threshold,  $T_{SHDN}$ , the IC shuts down and resets "O" type I<sup>2</sup>C registers. There is a 15°C thermal hysteresis. After thermal shutdown, if the die temperature reduces by 15°C, the thermal shutdown bus deasserts and the device re-enables. The battery charger has an independent thermal regulation loop, see the <u>Thermal Foldback</u> section for more details.

## Automatic Charger Loop Offset

The IC has four independent analog loops, including input voltage (AICL), input current, output voltage, and output current. The IC automatically switches between different loops and only one loop is in control at any time. Due to offset between different loops, the charger might hop between two loops at the boundary condition. For example, if the IC is in the fast-charge state and  $V_{BATT}$  is close to CHG\_CV\_PRM, and  $I_{BATT}$  is close to CHGCC, the charger is at the boundary of fast-charge CC state (output current loop) and fast-charge CV state (output voltage loop). The charger might hop between output current loop and output voltage loop continuously.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

To prevent possible loop hopping behavior, an automatic charger loop offset is implemented. Automatic offset of the output voltage loop (CHGR\_CV\_OFFSET[1:0]) and automatic offset of the output current loop (CHGCC\_OFFSET[1:0]) provide programmable hysteresis for entering these loops. The offset is applied when the charger is not in the corresponding loop and is automatically removed if the charger transitions to the corresponding loop. For example, if CHGR\_CV\_OFFSET[1:0] is set to 0x1 (+24mV), the fast-charge CC to CV transition occurs at V<sub>BATT</sub> equal to (CHG\_CV\_PRM + 24mV), and V<sub>BATT</sub> regulation target in the fast-charge CV state remains at CHG\_CV\_PRM. This creates extra hysteresis and maintains accurate regulation of each loop.

Adding automatic offset to a loop can prevent possible hopping with all other three loops. It is recommended that the user set:

- CHGCC\_OFFSET[1:0] to 0x01 for +62.5mA
- CHGR\_CV\_OFFSET[1:0] to 0x01 for +24mV

Offsets for the input current loop and input voltage (AICL) loop are set in OTP. The input current loop offset OTP\_INLIM\_OFFSET[1:0] is 0x0 (0mA/disabled), and the input voltage (AICL) loop offset OTP\_BYPV\_OFFSET[1:0] is set to 0x1 (-1 LSB). (The LSB is 175mV at VCHGIN\_REG = 4.025V—4.900V, 525mV at VCHGIN\_REG = 5.425V—10.950V, or 600mV at VCHGIN\_REG = 11.550V—19.050V).

Setting the automatic offset to 0x0 effectively disables this feature.

### Factory Ship Mode

The IC supports factory ship mode with low battery quiescent current, I<sub>SHDN</sub>.

When the input source is not valid, and the device is powered by battery, the device enters factory ship mode if STBY pin is pulled high or FSHIP\_MODE bit is set to 1. I<sup>2</sup>C communication is unavailable in the factory ship mode. When a valid input source is applied to the device's CHGIN pin or DISQBAT pin is pulled high, the device exits factory ship mode. I<sup>2</sup>C communication is enabled.

#### Minimum System Voltage

The system voltage is regulated to the minimum SYS voltage ( $V_{SYSMIN}$ ) when the battery is low ( $V_{BATT} < V_{SYSMIN}$  - 500mV).

- The charging current is I<sub>PRECHG</sub> when V<sub>BATT</sub> < V<sub>PRECHG</sub>.
- The charging current is I<sub>TRICKLE</sub> when V<sub>PRECHG</sub> < V<sub>BATT</sub> < V<sub>SYSMIN</sub> 500mV.
- The charging current is I<sub>FC</sub> when V<sub>SYSMIN</sub> 500mV < V<sub>BATT</sub>.

#### Battery Differential Voltage Sense (BATSP, BATSN)

BAT\_SP and BAT\_SN are differential remote voltage sense lines for the battery. The ICs remote sensing feature improves accuracy and decreases charging time. The thermistor voltage is interpreted with respect to BAT\_SN. For best results, connect BATSP and BATSN as close as possible to the battery connector.

#### **Battery Overcurrent Alert**

Excessive battery discharge current can occur for several reasons such as exposure to moisture, a software problem, an IC failure, a component failure, or a mechanical failure that causes a short circuit. The battery overcurrent alert feature is enabled with B2SOVRC[3:0]; disabling this feature reduces the battery current consumption by I<sub>BOVRC</sub>.

When the battery (BATT) to system (SYS) discharge current ( $I_{BATT}$ ) exceeds the programmed overcurrent threshold for at least  $t_{BOVRC}$ , the  $Q_{BAT}$  switch closes to reduce the power loss in the IC. A B2SOVRC\_I and a BAT\_I interrupt are generated, BAT\_OK is cleared, and BAT\_DTLS reports an overcurrent condition. Typically, when the host processor detects this overcurrent interrupt it executes a housekeeping routine that tries to mitigate the overcurrent situation. If the processor cannot correct the overcurrent within  $t_{OCP}$ , then the IC turns off the DC-DC.

 $t_{OCP}$  time duration can be set through the B2SOVRC\_DTC register bit (battery to SYS overcurrent debounce time control): 0x0 (dflt):  $t_{OCP}$  = 6ms, 0x1:  $t_{OCP}$  = 100ms.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

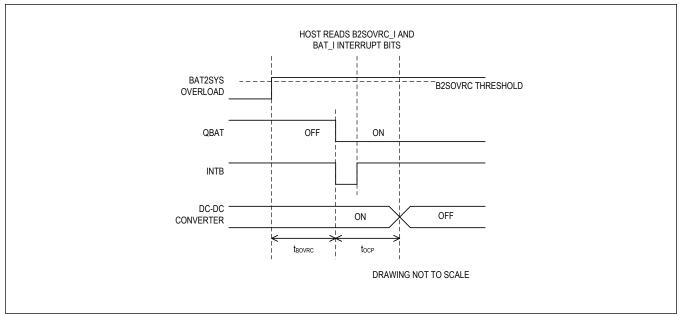

Figure 5. B2SOVRC

## Charger Interrupt Debounce Time

Debounce times of charger interrupts are listed in Table 8.

## **Table 8. List of Charger Interrupt Debounce Times**

	DEBOUNCE TIME						
INTERRUPT	RISI	NG	FALLING				
	MIN	MAX	MIN	MAX			
AICL_I	30ms	—	30ms				
CHGIN_I	7ms	—	None	_			
B2SOVRC_I	—	3.3ms	None				
BAT_I (OV)	30ms	—	None	—			
OTG_PLIM_I (OTG Fault)	37.5ms	—	None	—			
OTG_PLIM_I (Buck-Boost Positive Current Limit)	450us	—	None				

## Input Power-OK/OTG Power-OK Output (INOKB)

INOKB is an open-drain and active-low output that indicates CHGIN power-ok status.

When OTG mode is disabled, (OTGEN = L and MODE[3:0]  $\neq$  0x0A), INOKB pulls low when a valid input source is inserted at CHGIN, V<sub>CHGIN\_UVLO</sub> < V<sub>CHGIN\_OVLO</sub>.

When OTG mode is enabled, (OTGEN = H or MODE[3:0] = 0x0A), INOKB pulls low to indicate the OTG output power-OK when  $V_{CHGIN.OTG.UV} < V_{CHGIN.OTG.OV}$ .

INOKB can be used as a logic output by adding a  $200k\Omega$  pullup resistor to a system IO voltage.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

## Charge Status Output (STAT)

STAT is an open-drain and active-low output that indicates charge status. STAT can be used as a logic input to the host processor by adding a  $200k\Omega$  pullup resistor to a system IO rail and a rectifier (a diode and a capacitor).

## Table 9. Charge Status Indicator by STAT

CHARGE STATUS	STAT	LOGIC STATE
No input	High impedance	High
No DC-DC/no charge: Valid adapter with STBY_EN = 1 or MODE = 0x0/1/2/3/4	High impedance	High
Trickle, Precharge, Fast-Charge	Repeat low and high impedance with 1Hz, 50% duty cycle	High, rectified with an external diode and a capacitor
Top-Off and Done	Low	Low
Faults	High impedance	High

## **Reverse Buck Mode (OTG)**

The DC-DC converter topology of the MAX77962 allows it to operate as a forward buck-boost converter or as a reverse buck converter. The modes of the DC-DC converter are controlled with MODE[3:0] register bits. When MODE[3:0] = 0x0A or OTGEN = H, the DC-DC converter operates in reverse buck mode, allowing it to source current to CHGIN, commonly referred to as USB On-the-Go (OTG) mode.

Note that reverse buck mode of the MAX77962 conflicts with skip mode operation. Before enabling OTG function, disable skip mode with DISKIP = 1. Once OTG function is disabled, skip mode is allowed to be enabled with DISKIP = 0.

In OTG mode, the DC-DC converter operates in reverse buck mode and regulates  $V_{CHGIN}$  to  $V_{CHGIN.OTG}$  (5.1V, typ). The current through the CHGIN current sensing resistor (CSINN, CSINP) is limited to the value programmed by OTG\_ILIM[2:0]. There are four OTG\_ILIM options to program CHGIN current limit from 500mA to 1.5A. When the OTG mode is enabled, the unipolar CHGIN transfer function measures current going out of CHGIN. When OTG mode is disabled, the unipolar CHGIN transfer function measures current going into CHGIN.

OTG\_I, OTG\_M, and OTG\_OK are the interrupt bit, interrupt mask bit, and interrupt status bit associated with OTG function. OTG\_DTLS[1:0] reports the status of the OTG operation. OTG\_DTLS[1:0] is latched until the host reads the register.

If the external OTG load at CHGIN exceeds  $I_{CHGIN.OTG.ILIM}$  current limit for a minimum of 37.5ms, an OTG\_I interrupt is generated, OTG\_OK = 0, and OTG\_DTLS[1:0] = 01. The reverse buck operates as a current limited voltage source when overloaded. The DC-DC converter stops switching when the OTG\_ILIM condition lasts for 60ms and automatically resumes switching after 300ms OFF time. If the OTG\_ILIM fault condition at CHGIN persists, the DC-DC toggles ON and OFF with ~60ms ON and ~300ms OFF.

When CHGIN voltage drops below  $V_{CHGIN.OTG.UVLO}$ , the DC-DC stops switching and an OTG\_I interrupt is generated. OTG\_OK = 0 and OTG\_DTLS[1:0] = 00.

When CHGIN voltage exceeds  $V_{CHGIN.OTG.OV}$ , the DC-DC stops switching and an OTG\_I interrupt is generated. OTG\_OK = 0 and OTG\_DTLS[1:0] = 10.

If the DC-DC stops switching due to a OTG\_UV or OTG\_OV fault condition, it automatically retries after 300ms OFF time.

INOKB is the hardware indication of the OTG power-OK. See the <u>Input Power-OK/OTG Power-OK Output (INOKB)</u> section for details.

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### OTG Enable (OTGEN)

The OTGEN is an active-high input. When the OTGEN pin is pulled high, the OTG function is enabled. When the OTGEN pin is pulled low, the OTG function can be enabled through the  $I^2C$  interface by setting MODE[3:0] = 0x0A. Before enabling the OTG function, disable skip mode with DISKIP = 1. To pull the OTGEN pin low with a pulldown resistor, the resistance must be lower than  $44k\Omega$ .

The device enables reverse buck operation only when the voltage on the CHGIN bypass cap,  $V_{CHGIN}$ , falls below  $V_{CHGIN}$  UVLO.

In case  $V_{CHGIN}$  is above the  $V_{CHGIN}$  UVLO threshold at OTG enable, the device ensures the  $V_{CHGIN}$  node discharges through an  $8k\Omega$  pulldown resistor before enabling OTG function and reverse buck switching.

The pulldown is released once V<sub>CHGIN UVLO</sub> is reached.

### Analog Low-Noise Power Input (AVL)

AVL is the power input for the ICs analog circuitry. Do not power external devices from this pin. Bypass with a  $4.7\Omega$  resistor between AVL and PVL and a  $4.7\mu$ F capacitor from AVL to GND.

### Low-Side Gate Driver Power Supply (PVL)

PVL is an internal 1.8V LDO output, which powers the ICs low-side gate driver circuitry. Do not power external devices other than pullup resistors from this pin. Bypass with a 4.7µF capacitor to GND.

### System Faults

#### V<sub>SYS</sub> Fault

The IC monitors the  $V_{SYS}$  node for undervoltage and overvoltage events. The following describes the device's behavior if any of these events is to occur.

#### V<sub>SYS</sub> Undervoltage Lockout (V<sub>SYSUVLO</sub>)

When the voltage from SYS to GND ( $V_{SYS}$ ) is less than the undervoltage-lockout threshold ( $V_{SYSUVLO}$ ), the IC generates a SYSUVLO\_I interrupt immediately. If  $V_{SYS}$  is undervoltage for greater than 8ms, the device shuts down and resets "O" Type I<sup>2</sup>C registers.

#### V<sub>SYS</sub> Overvoltage Lockout (V<sub>SYSOVLO</sub>)

When the V<sub>SYS</sub> exceeds V<sub>SYSOVLO</sub>, the IC generates a SYSOVLO\_I interrupt immediately and the device shuts down and resets "O" Type I<sup>2</sup>C registers.

#### Thermal Fault

The IC has a die temperature sensing circuit. When the die temperature exceeds the thermal-shutdown threshold, 165°C (T<sub>SHDN</sub>), the IC shuts down and resets "O" Type I<sup>2</sup>C registers. There is a 15°C thermal hysteresis. After thermal shutdown, if the die temperature reduces by 15°C, the thermal shutdown bus deasserts and the IC re-enables. The battery charger has an independent thermal regulation loop. See the <u>Thermal Foldback</u> section for more details.

#### Interrupt Output (INTB)

The INTB is an active-low, open-drain output. Connect a pullup resistor to the pullup power source.

The ICs INTB can be connected to the host's interrupt input and signals to the host when unmasked interrupt events occur within the IC.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

## I<sup>2</sup>C Serial Interface

The I<sup>2</sup>C serial bus consists of a bidirectional serial-data line (SDA) and a serial clock (SCL). I<sup>2</sup>C is an open-drain bus. SDA and SCL require pullup resistors (500 $\Omega$  or greater). Optional 24 $\Omega$  resistors in series with SDA and SCL help to protect the device inputs from high voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot on bus lines.

### **System Configuration**

The I<sup>2</sup>C bus is a multi-master bus. The maximum number of devices that can attach to the bus is only limited by bus capacitance.

<u>Figure 6</u> shows an example of a typical I<sup>2</sup>C system. A device on I<sup>2</sup>C bus that sends data to the bus is called a transmitter. A device that receives data from the bus is called a receiver. The device that initiates a data transfer and generates SCL clock signals to control the data transfer is a master. Any device that is being addressed by the master is considered a slave. When the MAX77962 I<sup>2</sup>C-compatible interface is operating, it is a slave on I<sup>2</sup>C bus and it can be both a transmitter and a receiver.

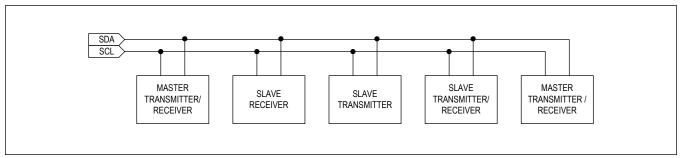

Figure 6. Functional Logic Diagram for Communications Controller

#### **Bit Transfer**

One data bit is transferred for each SCL clock cycle. The data on SDA must remain stable during the high portion of SCL clock pulse. Changes in SDA while SCL is high are control signals (START and STOP conditions).

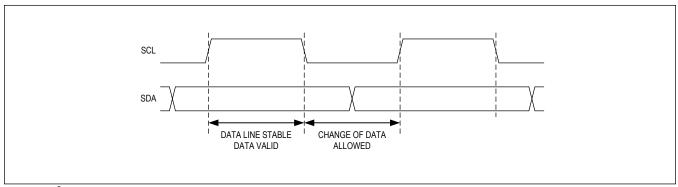

Figure 7. I<sup>2</sup>C Bit Transfer

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### START and STOP Conditions

When I<sup>2</sup>C serial interface is inactive, SDA and SCL idle high. A master device initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA, while SCL is high.

A START condition from the master signals the beginning of a transmission to the IC. The master terminates transmission by issuing a NOT ACKNOWLEDGE followed by a STOP condition.

STOP condition frees the bus. To issue a series of commands to the slave, the master can issue REPEATED START (Sr) commands instead of a STOP command in order to maintain control of the bus. In general, a REPEATED START command is functionally equivalent to a regular START command.

When a STOP condition or incorrect address is detected, the IC internally disconnects SCL from I<sup>2</sup>C serial interface until the next START condition, minimizing digital noise and feed-through.

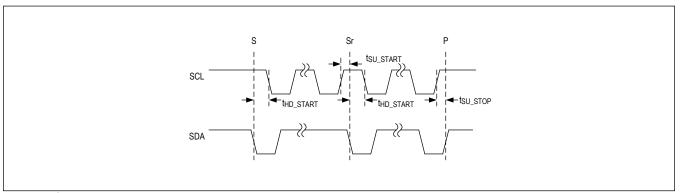

Figure 8. I<sup>2</sup>C Start Stop

#### Acknowledge

Both the I<sup>2</sup>C bus master and the IC (slave) generate acknowledge bits when receiving data. The acknowledge bit is the last bit of each nine bit data packet. To generate an ACKNOWLEDGE (A), the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse. To generate a NOT-ACKNOWLEDGE (nA), the receiving device allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves it high during the high period of the clock pulse.

Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

#### Slave Address

The IC acts as a slave transmitter/receiver. The slave address of the IC is 0xD2h/0xD3h. The least significant bit is the read/write indicator (1 for read, 0 for write).

#### **Clock Stretching**

In general, the clock signal generation for I<sup>2</sup>C bus is the responsibility of the master device. I<sup>2</sup>C specification allows slow slave devices to alter the clock signal by holding down the clock line. The process in which a slave device holds down the clock line is typically called clock stretching. The IC does not use any form of clock stretching to hold down the clock line.

#### General Call Address

The IC does not implement an I<sup>2</sup>C specification general call address. If the IC sees general call address (0000000b), it does not issue an ACKNOWLEDGE (A).

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

## **Communication Speed**

The IC provides I<sup>2</sup>C 3.0-compatible (1MHz) serial interface.

- I<sup>2</sup>C Revision 3 Compatible Serial Communications Channel
  - 0Hz to 100kHz (Standard Mode)
  - 0Hz to 400kHz (Fast Mode)
  - 0Hz to 1MHz (Fast-Mode Plus)
- Does not utilize I<sup>2</sup>C Clock Stretching

Operating in standard mode, fast mode, and fast-mode plus does not require any special protocols. The main consideration when changing the bus speed through this range is the combination of the bus capacitance and pullup resistors. Higher time constants created by the bus capacitance and pullup resistance (C x R) slow the bus operation. Therefore, when increasing bus speeds the pullup resistance must be decreased to maintain a reasonable time constant. Refer to the *"Pullup Resistor Sizing"* section of the I<sup>2</sup>C revision 3.0 specification for detailed guidance on the pullup resistor selection. In general, for bus capacitance of 200pF, a 100kHz bus needs 5.6k $\Omega$  pullup resistors, a 400kHz bus needs about a 1.5k $\Omega$  pullup resistors, and a 1MHz bus needs 680 $\Omega$  pullup resistors. Note that the pullup resistor dissipates power when the open-drain bus is low. The lower the value of the pullup resistor, the higher the power dissipation (V<sup>2</sup>/R).

Operating in high-speed mode requires some special considerations. For the full list of considerations, refer to the I<sup>2</sup>C 3.0 specification. The major considerations with respect to the IC are:

- I<sup>2</sup>C bus master uses current source pullups to shorten the signal rise times.
- I<sup>2</sup>C slave must use a different set of input filters on its SDA and SCL lines to accommodate for the higher bus speed.
- The communication protocols need to utilize the high-speed master code.

At power-up and after each STOP condition, the IC input filters are set for standard mode, fast mode, or fast-mode plus (i.e., 0Hz to 1MHz). To switch the input filters for high-speed mode, use the high-speed master code protocols that are described in the <u>Communication Protocols</u> section.

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

#### **Communication Protocols**

The IC supports both writing and reading from its registers.

#### Writing to a Single Register

<u>Figure 9</u> shows the protocol for the I<sup>2</sup>C master device to write one byte of data to the IC. This protocol is the same as SMBus specification's "Write Byte" protocol.

The "Write Byte" protocol is as follows:

- 1. The master sends a START command (S).
- 2. The master sends the 7-bit slave address followed by a write bit ( $R/\overline{W} = 0$ ).
- 3. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a data byte.
- 7. The slave acknowledges the data byte. At the rising edge of SCL, the data byte is loaded into its target register and the data becomes active.
- The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

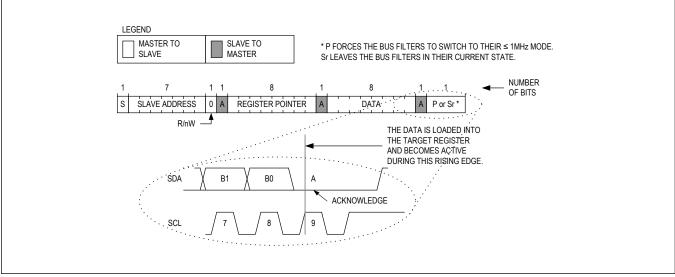

Figure 9. Writing to a Single Register

## 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### Writing to Sequential Registers

<u>Figure 10</u> shows the protocol for writing to sequential registers. This protocol is similar to the "Write Byte" protocol, except the master continues to write after it receives the first byte of data. When the master is done writing, it issues a STOP or REPEATED START.

The "Writing to Sequential Registers" protocol is as follows:

- 1. The master sends a START command (S).
- 2. The master sends the 7-bit slave address followed by a write bit (R/W = 0).
- 3. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a data byte.
- 7. The slave acknowledges the data byte. At the rising edge of SCL, the data byte is loaded into its target register and the data becomes active.
- 8. Steps 6 to 7 are repeated as many times as the master requires.
- 9. During the last acknowledge related clock pulse, the slave issues an ACKNOWLEDGE (A).
- The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a P ensures that the bus
  input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in
  their current state.

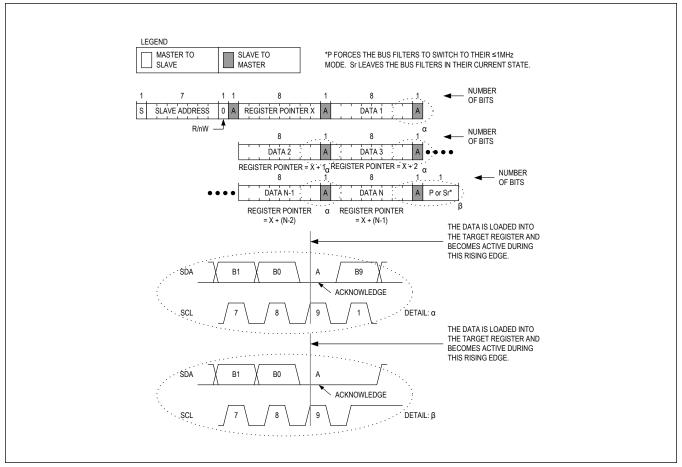

Figure 10. Writing to Sequential Registers

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### Writing Multiple Bytes using Register-Data Pairs

<u>Figure 11</u> shows the protocol for the I<sup>2</sup>C master device to write multiple bytes to the IC using register-data pairs. This protocol allows the I<sup>2</sup>C master device to address the slave only once and then send data to multiple registers in a random order. Registers may be written continuously until the master issues a STOP condition.

The "Multiple Byte Register-Data Pair" protocol is as follows:

- 1. The master sends a START command.
- 2. The master sends the 7-bit slave address followed by a write bit.
- 3. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a data byte.
- 7. The slave acknowledges the data byte. At the rising edge of SCL, the data byte is loaded into its target register and the data becomes active.
- 8. Steps 4 to 7 are repeated as many times as the master requires.
- 9. The master sends a STOP condition. During the rising edge of the stop related SDA edge, the data byte that was previously written is loaded into the target register and becomes active.

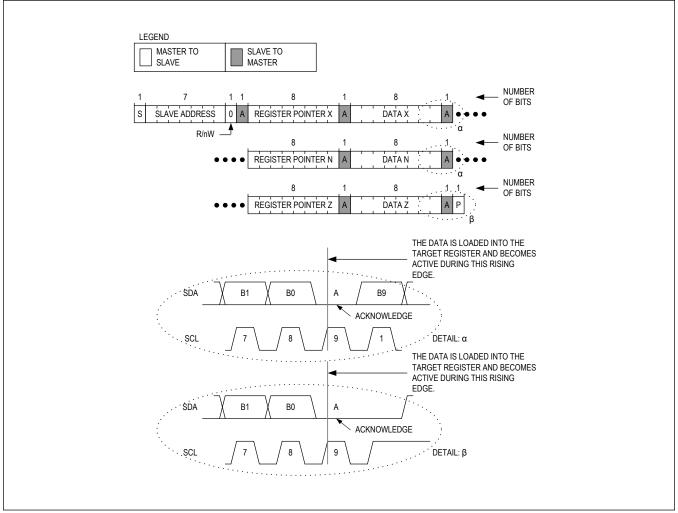

Figure 11. Writing to Multiple Registers with "Multiple Byte Register-Data Pairs" Protocol

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### Reading from a Single Register

The I<sup>2</sup>C master device reads one byte of data to the IC. This protocol is the same as SMBus specification's "Read Byte" protocol.

The "Read Byte" protocol is as follows:

- 1. The master sends a START command (S).
- 2. The master sends the 7-bit slave address followed by a write bit ( $R/\overline{W} = 0$ ).
- 3. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a REPEATED START command (Sr).
- 7. The master sends the 7-bit slave address followed by a read bit (R/W = 1).
- 8. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 9. The addressed slave places 8-bits of data on the bus from the location specified by the register pointer.
- 10. The master issues a NOT-ACKNOWLEDGE (nA).
- 11. The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

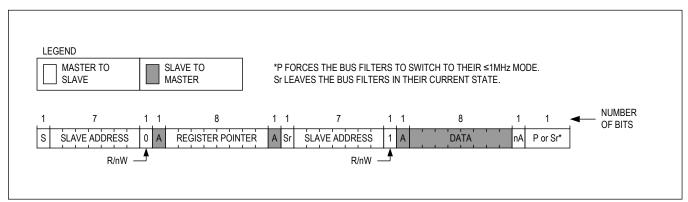

Figure 12. Reading from a Single Register

# 23V<sub>IN</sub> 3.2A<sub>OUT</sub> USB-C Buck-Boost Charger with Integrated FETs for 2S Li-Ion Batteries

### Reading from Sequential Registers

Figure 13 shows the protocol for reading from sequential registers. This protocol is similar to the "Read Byte" protocol except the master issues an ACKNOWLEDGE (A) to signal the slave that it wants more data—when the master has all the data it requires, it issues a not-acknowledge (nA) and a STOP (P) to end the transmission.

The "Continuous Read from Sequential Registers" protocol is as follows:

- 1. The master sends a START command (S).
- 2. The master sends the 7-bit slave address followed by a write bit (R/W = 0).
- 3. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4. The master sends an 8-bit register pointer.
- 5. The slave acknowledges the register pointer.
- 6. The master sends a REPEATED START command (Sr).
- 7. The master sends the 7-bit slave address followed by a read bit (R/W =1).
- 8. The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 9. The addressed slave places 8-bits of data on the bus from the location specified by the register pointer.
- 10. The master issues an ACKNOWLEDGE (A) signaling the slave that it wishes to receive more data.
- 11. Steps 9 to 10 are repeated as many times as the master requires. Following the last byte of data, the master must issue a NOT-ACKNOWLEDGE (nA) to signal that it wishes to stop receiving data.
- 12. The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a STOP (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

CHGCC	7:0	Fast-Charge Current Selection (mA). When the charger is enabled, the charge current limit is set by these bits. Read back value of the CHGCC register reflects the actual fast-charge current programmed in the charger. The thermal foldback loop can reduce the battery charger's target current by A <sub>TJREG</sub> .	$\begin{array}{l} 0x000: 50\\ 0x001: 56.25\\ 0x003: 68.75\\ 0x004: 75\\ 0x005: 81.25\\ 0x006: 87.5\\ 0x006: 87.5\\ 0x006: 125\\ 0x006: 100\\ 0x009: 106.25\\ 0x00A: 112.5\\ 0x00B: 118.75\\ 0x00C: 125\\ 0x00D: 131.25\\ 0x00D: 131.25\\ 0x00D: 131.25\\ 0x00F: 143.75\\ 0x00F: 143.75\\ 0x011: 156.25\\ 0x011: 156.25\\ 0x011: 156.25\\ 0x013: 168.75\\ 0x014: 175\\ 0x015: 181.25\\ 0x016: 187.5\\ 0x016: 187.5\\ 0x017: 193.75\\ 0x018: 200\\ 0x019: 206.25\\ 0x014: 212.5\\ 0x011: 231.25\\ 0x011: 231.25\\ 0x012: 255\\ 0x012: 255\\ 0x012: 255\\ 0x012: 262.5\\ 0x022: 262.5\\ 0x023: 268.75\\ 0x023: 268.75\\ 0x024: 275\\ 0x025: 281.25\\ 0x026: 287.5\\ 0x027: 293.75\\ 0x026: 287.5\\ 0x026: 287.5\\ 0x027: 293.75\\ 0x026: 331.25\\ 0x027: 331.25\\ 0x033: 368.75\\ 0x033$
