

Subtle Physiology of the Soul Layer

- The core pierces the edge at the top of the structure, thrusting pure source light downward in a triple-current stream made up of a blue function current, red purpose current and a yellow-gold wisdom current.
- As the core enters the soul layer the currents split off of the core into three single-current streams. These swoop out spinning in circles and swirls leaving about 50% of the energy continuing to move downward in a core. As the three streams move inside the soul layer, they cross each other repeatedly and fill the soul layer with a wild, swimming, rainbow of multi-colored light.
- The rest of the core travels across the soul layer and bisects the entire structure, exiting at the base, transiting the soul layer for a second time.
- The soul layer acts as a holding tank for the currents of the triple-current streams, as they separate, filter and refresh moving constantly. New Source energies entering all the time at the core and continue making fresh fuel for the structure.
- At the edge, is the outermost skin of the subtle structure covered with billions of tiny receptors. From each protrudes a small hair-like antenna. These hair-like antennae and receptors give the edge a fuzzy appearance. The villi and antennae attract pure energies as they emanate from the Source. The edge is where clean, unbiased contact is made with pure life force; where you can make friends with these universal energies.
- In the soul layer, eddies of swirling light are spinning anywhere from 8'-20' out from the bio layer. The soul layer is swirling with rainbow light and is unorganized and chaotic.
- In a big space, the structure will expand to fill the area we *need to* or *feel we need to* be effective. The ability to expand and contract is a natural function of the structure.
