INTRODUCTION

The oral route remains the preferred route of drug administration due to its convenience, good patient compliance and low production costs. In order for a drug to be absorbed into the systemic circulation following oral administration, the drug must be dissolved in the gastric fluids. For hydrophobic drugs, the dissolution process acts as the rate-controlling step and which determines the rate and degree of absorption. Bioavailability of poorly water soluble drugs is limited by their solubility and dissolution rate.

Liquisolid technique is a new and promising method that can change the dissolution rate of drugs. It has been used to enhance dissolution rate of poorly water-soluble drugs. The new 'liquisolid' technique may be applied to formulate liquid medications (i.e. oily liquid drugs and solutions, suspensions or emulsions of water-insoluble solid drugs carried in non-volatile liquid vehicles) into powders suitable for tableting or encapsulation. Since, the liquisolid tablets contain a solution of the drug in suitable solvent; the drug surface available for dissolution is tremendously increased.

The concept of orodispersible tablet emerged with an objective to improve patient's compliance. These dosage forms rapidly disintegrate and/or dissolve to release the drug as soon as they come in contact with saliva, thus without the need for water during administration, an attempts that makes them highly attractive for paediatric and geriatric patients.^[1] When put in the mouth, these dosage forms disintegrate instantly to release the drug, which dissolves or disperses in the saliva. Thereafter, the drug may get absorbed from the pharynx and oesophagus or from other sections of GIT as the saliva travels down. In such cases, bioavailability is significantly greater than that observed from conventional tablet dosage form.

LIQUISOLID SYSTEM

This technique was first introduced by Spireas et al. and applied to incorporate water insoluble drugs into rapid release solid dosage forms. The term "liquisolid

compacts" as described by Spireas et.al indicates that immediate or sustained release tablets or capsules that are prepared using the technique of "liquisolid systems" combined with the inclusion of appropriate adjuvants required for tabulating or encapsulation such as lubricants and for rapid or sustained release action, such as disintegrate or binders, respectively

CONCEPT OF LIQUISOLID SYSTEM^[2]

When the drug dissolved in the liquid vehicle is incorporated into a carrier material which has a porous surface and closely matted fibres in its interior such as celluloses, both absorption and adsorption take place. The liquid initially absorbed in the interior of the particles is captured by its internal structure. After the saturation of this process, adsorption of the liquid onto the internal and external surfaces of the porous carrier particles occurs. Then, the coating material having high adsorptive properties and large specific surface area provides the liquisolid system the desirable flow characteristics.

In liquisolid systems, the drug is already in solution form in liquid vehicle, while at the same time, it is carried by powder. The wettability of the compacts in the dissolution media is one of the proposed mechanisms for explaining the enhanced dissolution rate from the liquisolid compacts.

Fig-1: Theoretical Concept of Liquisolid System.

Non-volatile solvent present in the liquisolid system facilitates wetting of drug particles by decreasing interfacial tension between dissolution medium and tablet surface. Thus, due to substantial increase in wettability and effective surface area for dissolution, liquisolid compacts may be expected to reveal enhanced release profiles of water-insoluble drugs.

MATHEMATICAL MODEL TO DESIGN LIQUISOLID SYSTEM

For getting good flow behaviour and compressibility of liquisolid systems, a mathematical model designed by Spireas *et al.* was used as formulation design model for the liquisolid tablets. Prerequisites for this include suitable drug candidate, suitable non-volatile solvent, carrier and coating materials. The amounts of excipients (carrier and coating materials) used to prepare liquisolid compacts depend on the flowable liquid retention potential values (Φ -value) and the liquid loading factors (Lf)

Flowable liquid retention potential values (Φ -value)

The flowable liquid retention potential (Φ -value) of a powder is defined as the maximum amount of a given non-volatile liquid that can be retained inside its bulk (w/w) while maintaining acceptable flowability.

Therefore, in order to calculate the quantity of excipients, we need to determine the liquid retention potential value for both carrier (Φ_{CA} -value) and coating (Φ_{CO} -value) materials for each formulation. These values are constant for the given vehicle/powder system.

Liquid loading factors (Lf)

It is defined as the weight ratio of the liquid formulation (W) and the carrier material (Q) in the system.

$$Lf = W/Q \text{----- (1)}$$

(W is the weight of the liquid medication (the drug + non-volatile liquid vehicle) and Q is the weight of the carrier.)

R represents the **ratio** between the weights of the carrier (Q) and the coating (q) material present in the formulation. Then optimum weight of the coating material (q) could also be obtained (Equation 2).

$$R = Q/q \text{----- (2)}$$

The liquid load factor that ensures acceptable flowability (Lf) can be determined by.

$$Lf = \Phi_{CA} + \Phi_{CO} (1/R) \text{----- (3)}$$

By calculating Lf and W, we can calculate the amount of Q and required for the liquisolid system

Table-1: Liquisolid Formulation Parameters of Various Powder Excipients With Commonly Used Liquid Vehicles.^[3]

Non-volatile solvents	Φ -value for carrier material (Avicel PH102)	Φ -value for coating material (Aerosil 200)
1. Propylene glycol	0.16	3.31
2. polyethylene glycol 400	0.005	3.26
3. Tween 80	0.003	3.95
4. Cremophor EL	0.18	0.80
5. capryol 90	0.16	0.40

COMPONENTS OF LIQUISOLID SYSTEMS^[4,5]

The major formulation components of liquisolid compacts are.

1. Carrier material

These are compression-enhancing, relatively large, preferably porous particles possessing a sufficient absorption property which contributes in liquid absorption.

E.g. various grades of cellulose, starch, lactose, sorbitol, Avicel PH 102 and 200, Eudragit RL and RS, amorphous cellulose etc.

2. Coating material

These are flow-enhancing, very fine (10 nm to 5,000 nm in diameter), highly adsorptive coating particles (e.g., silica of various grades like Cab-O-Sil M5, Aerosil 200, Syloid 244FP etc.) contributes in covering the wet carrier

particles and displaying a dry-looking powder by adsorbing any excess liquid.

3. Non-volatile solvents

Inert, high boiling point, preferably water-miscible and not highly viscous organic solvent systems. Various non-volatile solvents used for the formulation of liquisolid systems include Polyethylene glycol 200 and 400, glycerin, polysorbate 80 and propylene glycol, polysorbates, glycerin, N, N- dimethylacetamide, fixed oils, etc.

4. Disintegrant

Superdisintegrants increases the rate of drug release, water solubility and wettability of liquisolid granules. Mostly Superdisintegrants like sodium starch glycolate and croscarmellose sodium are used.

MECHANISMS OF ENHANCEMENT OF DRUG RELEASE^[6, 7]

Several mechanisms of enhanced drug release have been postulated for liquisolid systems. The three main proposed mechanisms include increased surface area of drug available for release, increased aqueous solubility of the drug due to presence of non-volatile vehicle and improved wettability of the drug particles due to co solvent effect of the vehicle used.

A. Increased Effective Surface Area

If the drug within the liquisolid system is completely dissolved in the liquid vehicle, it is located in the powder substrate still in a solubilised and molecularly dispersed state. Therefore, the surface area of drug available for release is much greater than that of drug particles within directly compressed tablets.

B. Increased Aqueous Solubility

In addition to the first mechanism of drug release enhancement, it is expected that the solubility of the drug might be increased with liquisolid systems. In fact, the relatively small amount of liquid vehicle in a liquisolid compact is not sufficient to increase the overall solubility of the drug in the aqueous medium.

C. Improved Wetting Properties

Due to the fact that the liquid vehicle can either act as surface active agent or has a low surface tension, wetting of the primary liquisolid particles is improved.

Fig-2: Wetting Property of Liquisolid System.

Wettability of these systems can be demonstrated by contact angles and water rising times. Also the adsorption of the drug on the carrier particles increases the effective surface area, improving the contact of drug and wettability.

ADVANTAGES

Liquisolid tablets have many advantages. These include:

- Liquisolid systems are low cost formulations than soft gelatine capsules.
- Drug release can be modified using suitable formulation ingredients.
- Drug can be molecularly dispersed in the formulation.
- Capability of industrial production is also possible.
- Enhanced bioavailability can be obtained as compared to conventional tablets.
- Several slightly and very slightly water-soluble and practically water-insoluble liquid and solid drugs can be formulated into liquisolid systems.
- Even though the drug is in a tablet or capsule form, it is held in a solubilised liquid state, which contributes to increased drug wetting properties, thereby enhancing drug dissolution.^[8]
- Rapid release liquisolid tablets or capsules of water insoluble drugs exhibit enhanced In-vitro and in-vivo drug release when compared to their commercial counter parts, including soft gelatin capsules preparation.
- Sustained release liquisolid tablets or capsules of water insoluble drugs exhibit constant dissolution rates (zero-order release) comparable only to expensive commercial preparations that combine osmotic pump technology and laser-drilled tablets.
- Better availability of an orally administered water insoluble drug.
- Production of liquisolid systems is similar to that of conventional tablets.
- Can be used for formulation of liquid oily drugs.
- Can be used in controlled drug delivery.

LIMITATIONS

- Not applicable for formulation of high dose insoluble drugs.
- If more amount of carrier is added to produce free-flowing powder, the tablet weight increases to more than one gram which is difficult to swallow.
- Acceptable compression properties may not be achieved since during compression liquid drug may be squeezed out of the liquisolid tablet resulting in tablets of unsatisfactory hardness.

APPLICATIONS^[9, 10, 11]

- Liquisolid compact technology is a powerful tool to improve bioavailability of water insoluble drugs. Several water insoluble drugs on dissolving in different non-volatile solvents have been formulated into liquisolid compacts.
- Different drugs can be incorporated into liquisolid compacts.

- Rapid release rates.
- Used for water insoluble solid drugs or liquid lipophilic drugs.
- Sustained release of drugs.
- Solubility and dissolution improvement.
- Flowability and compressibility.
- Designing of controlled release tablets.
- Bioavailability enhancement.
- Application in probiotics.
- Improvement of drug photostability.

ORODISPERSIBLE TABLETS

The US Food and Drug Administration Center for Drug Evaluation and Research (CDER) defines, in the 'Orange Book', an ODT as "a solid dosage form containing medicinal substances, which disintegrates rapidly, usually within a matter of seconds, when placed upon the tongue". The significance of these dosage forms is highlighted by the adoption of the term, "Orodispersible Tablet", by the European Pharmacopoeia which describes it as a tablet that can be placed in oral cavity where it disperses rapidly before swallowing.

DRUG SELECTION CRITERIA FOR ODTs

- Able to saturate the oral mucosa.
- At least moderately non-ionized at oral cavity pH.
- Have the ability to diffuse and partition into the epithelium of upper GIT.
- Small to moderate molecular weight
- Low dose drugs mostly less than 50 mg.
- Should have good stability in saliva and water.
- Drugs with lower bio availability are good candidates for ODT.
- Frequent dosing drugs are unsuitable for ODT.

CHALLENGES AND LIMITATIONS FOR ODTs^[14, 15]

- Drugs with relatively larger doses are difficult to formulate into ODTs e.g. antibiotics like ciprofloxacin with adult dose tablet containing about 500 mg of the drug.^[12]
- Mechanical strength - ODTs are made of porous or soft molded matrices in order to allow its disintegration in mouth. This makes tablet friable and handling becomes difficult.
- Orodispersible tablets with highly porous structure and good mechanical strength have been developed by sublimation method.
- Palatability - ODTs are intended to be dissolved in mouth. Most of the drugs have bitter taste. Bitter taste can be masked with enough sweetener and flavors.
- Drugs in form of ODTs are hygroscopic in nature and hence need to be protected from humidity.^[13] To overcome humidity problem special working facilities can be designed by simple methods and special air-conditioning systems can be set up.
- Size of tablet -7mm is easy to swallow while tablets of size 8mm are easy to handle. Hence, tablet sizes which are both easy to handle and swallow are

difficult to achieve. For the patient compliance, to make the swallowing easier, round shape punches having optimum dimensions are used.

- Drug candidates should be stable both in water and in saliva, should not ionize at oral cavity pH and should be able to permeate oral mucosal tissue to diffuse and partition in upper GI epithelium ($\log P > 1$, or preferably > 2 , should not have short half-life). To optimize solubility problem of the active pharmaceutical ingredient some solid buffers and surfactants can also be chosen.
- ODT requires special packaging for proper stabilization and safety of stable product.

ADVANTAGES^[16, 17]

1. Administration to the patients who cannot swallow, such as the elderly, stroke victims, bedridden patients, patients affected by renal failure & patients who refuse to swallow such as paediatric, geriatric & psychiatric patients.
2. Rapid drug therapy.
3. Increased bioavailability/rapid absorption through pregastric absorption of drugs from mouth, pharynx & oesophagus as saliva passes down.
4. Better patient compliance for disabled, bedridden patients, travellers and busy people, who do not always have access to water.
5. Good mouth feel property helps to change the perception of medication as bitter pill particularly in paediatric patients.
6. The risk of choking during oral administration of conventional formulations due to physical obstruction is avoided, thus providing improved safety.

METHOD OF PREPARATION OF ORODISPERSIBLE LIQUISOLID SYSTEM

As shown in figure-3, a liquid drug can be converted into a dry liquisolid system without being further chemically modified. If liquisolid system of a solid water-insoluble drug is to be formulated, it should be initially dissolved or suspended in a suitable non-volatile solvent system to produce a drug solution or drug suspension of desired concentration.

Next, a certain amount of the prepared drug solution or suspension or a liquid drug itself is incorporated into a specific quantity of carrier material which should be preferably of a porous nature and possessing sufficient absorption properties.

The resulting wet mixture is then converted into a dry, non adherent, free-flowing and readily compressible powder by the simple addition and mixing of a calculated amount of coating material.

Excipients possessing fine and highly adsorptive particles are suitable for this step. Before compression or encapsulation, various adjuvants like lubricants and

super-disintegrants added to final liquisolid system to produce orodispersible liquisolid compacts.

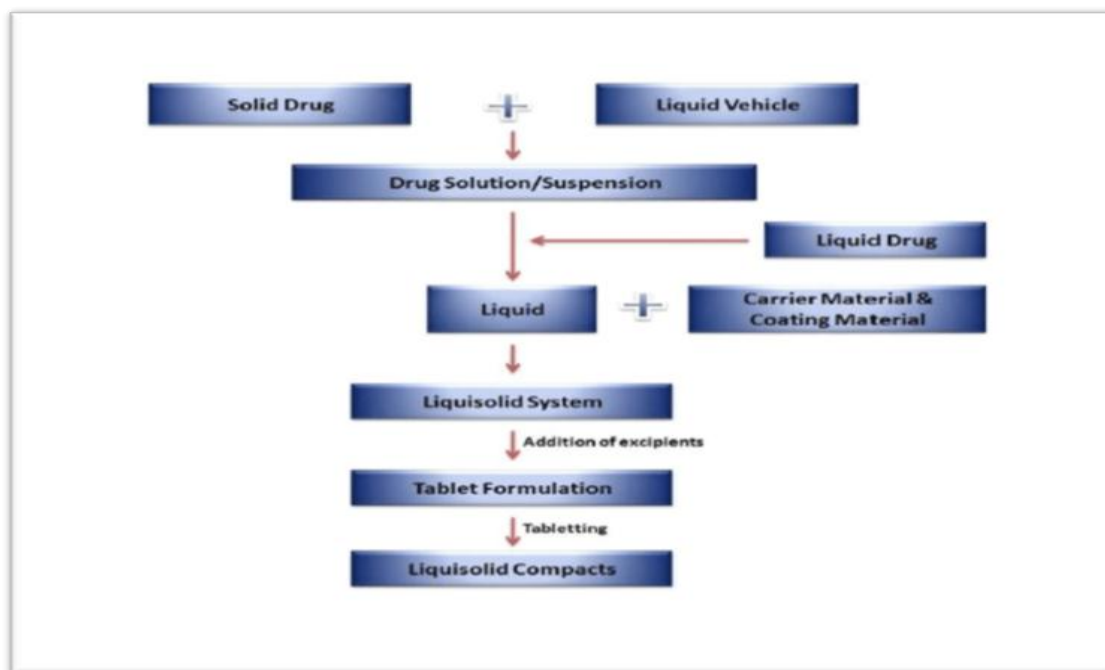

Fig-3: Steps Involved In The Preparation of Liquisolid System.

PRE-FORMULATION STUDIES

1. Solubility studies^[18, 19]

Solubility studies are carried out by preparing saturated solutions of drug in non-volatile solvent and analyzing them spectrophotometrically. Saturated solutions are prepared by adding excess of drug to non volatile solvent and shaking them on shaker for specific time period under constant vibration. After this, the solutions are filtered and analyzed spectrophotometrically.

2. Determination of angle of slide^[20]

Angle of slide is used as a measure of the flow properties of powders. Determination of angle of slide is done by weighing the required amount of carrier material and placed at one end of a metal plate with a polished surface. The end is gradually raised till the plate becomes angular to the horizontal at which powder is about to slide. This angle is known as angle of slide. Angle of 33° is regarded as optimum.

3. Determination of flowable liquid retention potential (Φ -value)^[20, 22]

The term "flowable liquid- retention potential" (Φ -value) of a powder material describes its ability to retain a specific amount of liquid while maintaining good flow properties. The Φ -value is defined as the maximum weight of liquid that can be retained per unit weight of the powder material in order to produce an acceptably flowing liquid/powder admixture. The Φ values are calculated according to equation

$$\Phi \text{ value} = \text{weight of liquid} / \text{weight of solid} \dots (4)$$

4. Calculation of liquid load factor (Lf)^[21, 23]

Different concentrations of non-volatile solvents are taken and the drug is dissolved. Such liquid medication is added to the carrier-coating material admixture and blended. Using equation (5) drug loading factors are determined and used for calculating the amounts of carrier and coating materials in each formulation.

$$\text{Lf} = \text{weight of liquid medication} / \text{weight of carrier material} \dots (5)$$

5. Liquisolid compressibility test (LSC)

The Liquisolid compressibility test is used to determine Φ values and involves steps such as preparing carrier coating material admixture systems, preparing several uniform liquid or powder admixtures, compressing each liquid or powder admixtures to tablets, assessing the average hardness, determination of the average liquid content of crushed tablets, as well as determining plasticity, sponge index and Φ value and Lf.

CONCLUSION

The Liquisolid system is a technique for formulation of water insoluble drugs to enhance their aqueous solubility, absorption as well as dissolution rate which leading to enhancement of bioavailability of drugs as compared to conventional directly compressed tablets. Orodispersible tablets may give rapid onset of action by rapid absorption through pre-gastric absorption of drug from mouth, pharynx and oesophagus as saliva passes down and beneficial to reduce dose. By combining Liquisolid technique and Orodispersible DDS, may enhance solubility, dissolution rate by means of Liquisolid technique and can achieve rapid onset of

action with lower dose of drug by using Orodispersible DDS and hence may increase patient compliance.
