NPCC Glossary of Terms, dated January 18, 2012

Introductions and Chair's Remarks

NPCC Antitrust Compliance Guidelines

Agenda Items:

1.0 Review of Agenda

2.0 RSC Meeting Minutes

3.0 Drafting Team Members and Executive Tracking Summary

3.1 NPCC Members on NERC Drafting Teams
3.2 Executive Tracking Summary
3.3 NERC Project Tracking Spreadsheet

4.0 Open Action Items

4.1 Open Action Items List

5.0 Items Requiring RSC Discussion / Approval

5.1 NERC Weekly Standards Bulletin
5.2 Approval of RSAR Regional Variance -PRC-006-3--Automatic Underfrequency Load Shedding - Variance for the Quebec Interconnection
5.3 NERC IGTF Report
5.4 2010-05.3 Phase 3 of Protection Systems: Remedial Action Schemes (RAS)
5.5 FERC NOPR of GMD HQT Presentation
5.6 TOP-IRO NOPR RM15-16-000
Mr. Ben Li will call in at 2PM to discuss the issue.

6.0 NERC Reliability Standards

November 20	December 18	

Respectfully Submitted,

Guy V. Zito, Chair RSC
Assistant Vice President-Standards
Northeast Power Coordinating Council, Inc.

Northeast Power Coordinating Council, Inc. (NPCC)

Antitrust Compliance Guidelines

It is NPCC's policy and practice to obey the antitrust laws and to avoid all conduct that unreasonably restrains competition. The antitrust laws make it important that meeting participants avoid discussion of topics that could result in charges of anti-competitive behavior, including: restraint of trade and conspiracies to monopolize, unfair or deceptive business acts or practices, price discrimination, division of markets, allocation of production, imposition of boycotts, exclusive dealing arrangements, and any other activity that unreasonably restrains competition.

It is the responsibility of every NPCC participant and employee who may in any way affect NPCC's compliance with the antitrust laws to carry out this commitment.

Participants in NPCC activities (including those participating in its committees, task forces and subgroups) should refrain from discussing the following throughout any meeting or during any breaks (including NPCC meetings, conference calls and informal discussions):

- Industry-related topics considered sensitive or market intelligence in nature that are outside of their committee's scope or assignment, or the published agenda for the meeting;
- Their company's prices for products or services, or prices charged by their competitors;
- Costs, discounts, terms of sale, profit margins or anything else that might affect prices;
- The resale prices their customers should charge for products they sell them;
- Allocating markets, customers, territories or products with their competitors;
- Limiting production;
- Whether or not to deal with any company; and
- Any competitively sensitive information concerning their company or a competitor.

Any decisions or actions by NPCC as a result of such meetings will only be taken in the interest of promoting and maintaining the reliability and adequacy of the bulk power system.

Any NPCC meeting participant or employee who is uncertain about the legal ramifications of a particular course of conduct or who has doubts or concerns about whether NPCC's antitrust compliance policy is implicated in any situation should call NPCC's Secretary, Ruta Skučas, Esq. at 1-202-470-6428.

Introductions and Chair's Remarks

Guy Zito called the meeting to order at 10:00 a.m. on Wednesday April 22, 2015.

He introduced Lisa Moerner, Director of FERC, and Electric Market & NERC Compliance Policy at Dominion Resources Services.

Lisa Moerner welcomed the meeting participants and provided a short introduction to Dominion Resources Services.

Connie Lowe discussed the emergency evacuation procedures for the building and provided logistics for the meeting.

Guy Zito thanked Bruce Metruck and Si Truc Phan for accepting the roles of RSC vice chairs and noted their appointments had been approved by the NPCC Board of Directors.

NPCC Antitrust Compliance Guidelines

The NPCC Antitrust Compliance Guidelines were read by Lee Pedowicz.

Agenda Items:

1.0 Review of Agenda

The RSC Draft Meeting Agenda was reviewed by Guy Zito.

Guy Zito transferred 5.10 Draft ERO Event Analysis Process and Appendices – Version 3 to Section 14.4 on the RSC Draft Meeting Agenda.

Guy Zito adding an additional topic in Section 6.4 Vincent Morissette called in at 9:00 a.m. on Thursday April 23, 2015 to present Quebec's Variance for PRC-006-2.

Guy Zito removed Section 13.0 from future RSC meeting agendas.

Guy Zito added Section 5.11 to the Agenda for Jim Grant to discuss how the NYISO is going to address TOP registration issues for NY TOs and to explain how the Coordinated Functional Registrations would work.

2.0 RSC Meeting Minutes

Approval of Minutes: Final Meeting Minutes 2-18-15

Guy Zito suggested replacement language for the unresolved issue addressed in Section 5.3.Herb Schrayshuen suggested a revision to what was proposed.

Brian Robison made a motion for approval of the Minutes as revised.

Si Truc Phan seconded the motion.

The Meeting Minutes were approved as read.

3.0 Drafting Team Members and Executive Tracking Summary

3.1 NPCC Members on NERC Drafting Teams

John Ciufo from Hydro One has retired and needs to be removed from the NERC Standard Drafting Teams list. Mike Potishnak will be unable to continue on the BAL projects past this coming June. The importance of keeping the list up-to-date was stressed.

It was agreed to follow a suggestion made by Herb Schrayshuen to only include those projects that have not been finally approved.

Action Item: NPCC Standards Staff will review the Drafting Team list to ensure it is kept up-to-date.

3.2 Executive Tracking Summary

RuiDa Shu provided updates on the Executive Tracking Summary which is posted on the NPCC Website.

Guy Zito mentioned that at this time there is an indication there will be another "bow wave" of projects posted at the end of the year. NERC realizes this, and they will try and have some completed sooner, by August. With that accelerated schedule it will difficult to have the time to address standards' issues that arise.

3.3 NERC Project Tracking Spreadsheet

Guy Zito provided a brief update on the NERC Project Tracking Spreadsheet.

4.0 Open Action Items

4.1 Open Action Items List

Guy Zito provided updates on the Open Action Item list. Mike Jones reported that Compliance Committee members agreed that entities should send in their comments on RSAWs individually--there won't be a coordinated and consensus NPCC Compliance Committee submittal. How NPCC as a region will comment on RSAWs going forward remains an unresolved issue. Guy Zito will continue to pursue this

with NPCC Leadership. It was mentioned that NERC has been writing the RSAWs with little help, if any, from the drafting teams. .

Si Truc Phan said that Hydro-Quebec cannot share comments on RSAWs though CC. Guy Zito suggest to ensure individually someone in your organization is reviewing or cognizant of these postings directly to NERC.

Herb Schrayshuen asked what committee this issue should be brought to.

Guy Zito said that there is a gap in RSAW development, and the Compliance Committee does not believe it is in their role to pursue it. Questions asked were what the value in reviewing RSAWs is, and what is the value in sending in comments individually?

Ron Falsetti added that that the NPCC Board of Directors should make a decision on who should author comments on the RSAWs. The RSC Scope approved by the Board of Directors does not include RSAW review.

Item 4.2 NPCC outreach is removed from the Open Action Item List.

Item	Description	Owner	Due	Status
4.1	Coordination with the Compliance Committee to develop Joint Activity Action List	Greg Campoli	RSC Meeting	Ongoing Guy Zito decided to keep RSAWs for now.

5.0 Items Requiring RSC Discussion / Approval

5.1 NERC Weekly Standards Bulletin

Guy Zito mentioned this was an information item only.

5.2 NPCC RCC Meeting Minutes

Guy Zito recommended that Section 5.2 NPCC RCC Meeting Minutes be removed from the RSC Meeting Agendas going forward and that only pertinent standards or criteria related topics in the RCC meetings be related to the RSC members.

5.3 Primary RSC Members can't serve as Alternates in other sectors

Guy Zito said that this was an issue that was exposed by the recent revision to the Regional Delegation Agreement. Although there is no direct violation of the NPCC Revised and Restated Bylaws the matter has been resolved voluntarily by NPCC working with the members of the RSC.

5.4 Renegotiation of Regional Delegation Agreements

Guy Zito provided a brief description on the renegotiation of the Regional Delegation Agreement (RDA) document. An NPCC Regional Delegation Agreement will be good for five years, but can be extended to ten years. Further clarification for the Canadian relationships will be part of the new RDA.

5.5 Validation Testing of Minimum Vegetation Clearance Distances

Guy Zito provided additional information on the FAC-003 Research Project. This is a RAPA item and a study directed by the FERC indicated that the clearances as specified in the FAC-003 standard need to be increased. The current Gap Factor in the "Gallet" equation used for determining clearance to prevent flashover to vegetation needs to be reduced to 1.0 from 1.3. This will result in increased clearance of from 1.5 to three feet. Ron Falsetti said that a draft alert was sent out several days before this meeting. Not everyone got it. A SAR will be posted eventually to revise the clearance tables in the standard and a NERC Alert issued as well to notify the industry. It was noted that Compliance would audit only to the standard, not the Alert, SAR or study performed by RAPA.

5.6 NYPA Comments on CIP-002-5.1 Lessons Learned

Bruce Metruck provided updates on CIP-002-5.1 Lessons Learned. The issue was brought to the Compliance Committee and the RCC. In addition, meetings were held with NERC and NPCC staff. The issue is that when looking at any entity the RC, TOP, or BA are the ones that actually have to perform the analysis. NERC is considering developing a SAR to address this. Herb Schrayshuen suggested that industry should write the SAR. The SAR would address the definition of Control Center. The local control center issue still exists. Guy Zito said that with the standard already published, a SAR should not be perceived as weakening it. Suggested that an industry trade organization, such as CEEI, or APPA for example, should get involved. Bruce Metruck said that there was a meeting taking place today (April 22, 2015) where this issue is being addressed. It was his expectation something to be released today (April 22, 2015).

Brian Robinson indicated that there will be a communication sent out by NERC on this topic.

5.7 Review of the Documents on RSC NPCC Website

RuiDa Shu led the discussion. People had questioned where documents could be found on the NPCC Website. In response to an inquiry from Si Truc Phan, it was reported that all standards documents are public and entities don't have to be a member of NPCC to view the documents.

5.8 Project 2007-06.2 Phase 2 of System Protection Coordination

RuiDa Shu led the discussion. The Drafting Team is at point where a decision has to be made as to how the project is to be moved forward. Guy Zito said that the term "familiarity with protection systems" is a concern, and that FERC has been involved. RuiDa Shu will distribute an explanatory white paper when it becomes available (within several days after the RSC Meeting concludes). Ron Falsetti opined that the issue of demonstrating familiarity or knowledge of protection systems would be more appropriate in a PER standard.

5.9 Periodic Review Project 2010-14.2 BAL-005-0.2b and BAL-006-3

Guy Zito mentioned that the content of BAL-005 was moved into other standards. Si Truc Phan commented that BAL-006 involves commercial customers and it is not a reliability issue. BAL-005 should be looked at with respect to Paragraph 81. BAL-005 contents were put into BAL-001, and BAL-002.

5.10 Draft ERO Event Analysis Process and Appendices – Version 3

Brian Robinson indicated that draft document is posted for comment until May 30th, 2015.

Guy Zito said that RSC won't be submitting comments for this.

5.11 Jim Grant will provide a brief discussion on new TOP issues at NYISO.

Jim Grant led the discussion. The NYSIO-TO Agreement outlines what facilities it has operational control over. The TOs were required to give notification of what they operated. New facilities had to be added. The NYISO met with RCs to determine how this should be handled. Not everything is A-1. The TOs would be TOPs. Changes to how things are being done was minimized. There were minor changes made to the NYISO-TO Agreement. This takes effect July 1, 2016. The NYISO is prepared to enter into a Coordinated Functional Registration (CFR) agreement. The NYISO is now the TOP for only the A-10 list.

Bob Coughlin said that there are no new TOPs in New England. He sees no problems with adopting the new BES.

Jim Grant further indicated that to register as a TOP, a certification is required. New TOPs have to register by July 1st, 2015. By the end of 2015 all New York TOs should be certified as TOPs.

The NYISO will assume some of the 200KV TOP responsibilities.

5.12 Scott Nied from NPCC Compliance staff called in at 1p.m. to discuss compliance items, and risk-based registration. Scott will be working with TFSP, TFCP, TFCO and TFSS on risk-based registration and is also seeking the Canadian provinces to provide statement how their final BESs will support reliability.

Scott Nied also discussed the BES definition implementation.

Each of the NPCC Task Forces will provide a report on the impact of BES Elements on each Canadian providence.

6.0 NERC Reliability Standards

http://www.nerc.com/pa/Stand/Pages/Standards-Under-Development.aspx

6.1 Currently Posted Projects

Project	Comment Period End Date	Ballot Period End Date	Standards Developer	4/22/15 Call-In
Project 2008-02.2 Phase 2 of Undervoltage Load Shedding (UVLS): Misoperations			Scott Barfield-McGinnis	
Project 2014-04 Physical Security			Stephen Crutchfield	
Project 2007-06 System Protection Coordination	5/15/15	5/15/15	Al McMeekin	

	(F)	(A)		
Project 2015-02 Emergency Operations Periodic Review	5/11/15 (I)		Laura Anderson Chair: David McRee	1:45 p.m.
New Standards Balloting and Commenting System			Barbara Nutter	2:00 p.m.
Comments: (I) – Informal; (F) – Formal **Ballots:** (I) – Initial; (A) – Additional; (F) – Final				

Guy Zito mentioned that RSC recommended a yes vote for Project 2008-02.2.

Lou Oberski, the Chair of Project 2014-04 Physical Security, called into the meeting at 1:20 p.m. The Standard Drafting Team's target goal is to complete the project by October 1st, 2015 to address one of the FERC Directives. Suggestions were made to the SDT on an alternative word for "Widespread", which the FERC indicated needed to be removed from the standard. The Drafting Team removed the term "widespread" and did not attempt to clarify or replace the concept. The SDT has also made minor revision to the VRF and VSL tables. Don't have consensus though. Will be worked on after the final ballot.

The RSC reviewed Project 2007-06 PRC-027 as a group and identified no major issues. Guy Zito indicated that the project was posted for comment and an additional ballot would be held which would end on May 15, 2015.

David McRee, Chair of the SDT for Project 2015-02 called into the RSC meeting at 1:29 p.m. Attachment 1 was clarified in EOP-004-2. EOP-005-2 has requirements identified for retirement. EOP-006-2 has Parts 1.2, 1.3, and 1.4 identified for retirement. EOP-008 includes revisions to the Measure.

Posted for comments until May 11th, 2015. The SDT tried to retire all the redundant requirements. The SDT will use rationale boxes to address all the "soft" directives by FERC. If needed, a SAR will be included with the Project. The SDT is looking for industry comments specifically on the training portion of the EOP-005 and EOP-006 standards.

Connie Lowe led the discussion on the requirements for training in EOP-005-2, and EOP-006-2. The RSC mentioned training should be in PER-005.

Si Truc Phan asked if the Hydro Quebec requested change was made in the Attachment to 2000MW in reference to the Quebec variance, and David McRee indicated he thought that it was.

Barb Nutter from NERC called into the meeting at 1:55p.m. She led the discussion on NERC's new Standard Balloting System (SBS).
The new SBS has been in effect since February, 2015. NERC is working on being able to allow the site to make all comment submissions more easily visible. NERC is also working on having the system recognize the 8:00 p.m. submission close deadline. Barb indicated that the comment submission issue should be fixed by next week.

Barb Nutter noted that if a standard is posted for comment with no ballot, then comments can only be submitted once. If a Standard is posted with a ballot, then the commenter may resubmit the entire comment form.

Action Item: Lee Pedowicz needs to come up with a way to identify the group names in the Balloting and Commenting System.

6.2 Ballot History (Since last RSC Meeting)
Rui Da Shu reviewed the Ballot History.

6.3 Comment Form History (Since last RSC Meeting)
Rui Da Shu reviewed the Comment Form History document in the meeting.

6.4 Hydro-Quebec Variance for PRC-006-2.

6.5 PRC-012-2 - Remedial Action Scheme Review Procedure
Guy Zito discussed this item. Greg Campoli and others called in from the ISO/RTO Council Standards Review Subcommittee Meeting to discuss the draft standard and the drafting team's position. The main topic of discussion was the expanded potential role of the RCs in the review of the RAS. The existing SPS standards have the Regional Reliability Organization (RRO) listed as an applicable entity. Guy Zito noted that FERC, in Order 693 had ruled that the RRO, as listed in the standard, had a "fill-in-the-blank" aspect. Also discussed was the security vs. reliability issues associated with the SPS/RAS. It was the opinion of the ISO/RTO SRC that the PC was the more appropriate entity to conduct RAS reviews.

Vincent Morissette from Hydro Quebec called into the RSC Meeting at 9:00 a.m. April 23, 2015 to present the SAR for a Quebec Variance to continent-wide PRC-006-2 Automatic Underfrequency Load Shedding.

Action Item: NPCC Standards Staff will review the SAR submitted by Hydro Quebec and work to finalize it. NPCC will then transmit the SAR to NERC and be a joint "requester."

7.0 NERC Drafting Team Nominations

http://www.nerc.com/pa/Stand/Pages/Drafting-Team-Vacancies.aspx

7.1 Currently Posted Drafting Team Vacancies
- 7.1.1 None at this time

8.0 NPCC Regional Reliability Standards

https://www.npcc.org/Standards/default.aspx

8.1 Current Activities:

8.1.1 RSAR for Disturbance Monitoring Standard PRC-002-NPCC-01 SDT Roster

Guy Zito asked for a motion to approve the SDT Roster for the RSAR on PRC-002-NPCC-01.

Brian Robinson made a motion for approval.

Glen Smith seconded the motion.

The SDT Roster for Disturbance Monitoring PRC-002-NPCC-01 was approved as submitted.

8.1.2 RSAR for Automatic Underfrequency Load Shedding PRC-006-NPCC-1

Brian Robinson is the Requester of the RSAR.

Kelly Dash and Mike Jones both provided changes/updates to the RSAR for Automatic Underfrequency Load Shedding PRC-006-NPCC-1.

Action Item: NPCC Standards Staff will review the RSAR with the changes suggested and handle appropriately. The final RSAR will be brought to the RSC for approval at the June 2015 meeting

8.2 Activities on Hold: Regional Standard BAL-002-NPCC-01: Regional Reserve Sharing

9.0 NPCC Non-Standards

https://www.npcc.org/Standards/SitePages/NonStandardsList.aspx

9.1 Directories:

9.1.1 Directory #1 Design and Operation of the Bulk Power System (Status of CO7/CP11 Review).

Current Status: update on Mr. Dunbar's 1/26/15 email message to the RSC (List of ERO Standards in each Directory).

The CO7/CP11 Working Group reviewing Directory#1 has proposed removing the list of ERO standards associated with Directory#1 from the document. RSC has been asked to consider whether such lists should also be removed from all other NPCC Directories.

RSC requested the development of a list that would allow the RSC to consider the pros and cons of removing the list of associated ERO standards from all NPCC Directories.

Gerry Dunbar reviewed the pros and cons list with the RSC members.

Herb Schrayshuen suggested adding another con to the list: maintaining the ERO Standards list in their associated directories will be an additional administrative burden on the NPCC Standards Staff.

Mr. Zito conducted an informal poll of the RSC Members. There was majority agreement to leave the list of associated ERO standards in Directory #1 and all other NPCC Directories.

9.1.2 Directory #3 Maintenance Criteria for BPS Protection – (Retired effective April 1st, 2015 to coincide with the enforcement date of PRC -005-2 *Protection System Maintenance*.).

9.1.3 Directory #7 SPS (Status of NERC RAS)

Mr. Zito discussed the status of Project 2010-05-3 Phase 3 of Protection Systems: Remedial Action Schemes (RAS) PRC -012-2. Mr. Zito stated that the revised standard will be impactful for RSC Members and in particular the Reliability Coordinators (R.C.s).

The standard drafting team (SDT) is proposing that the R.C. be assigned applicability for reviewing and approving protection systems classified as a RAS.

Mr. Zito noted that currently NPCC Task Forces perform this review/ approval and there is concern that the R.C. may not have the expertise to adequately consider all aspects of a RAS design.

NPCC is participating as an observer on the drafting team and HQT is also represented and participating on the SDT.

PRC -012-2 will be posted for an informal comment period on April 29th, 2015 in order for the SDT to solicit industry comment and suggestions on the draft standard.

Mr. Zito discussed the issue of redundancy which has been proposed for those RAS that are designed to achieve compliance with the TPL standards.

Mr. Zito suggested that the redundancy requirement has the potential to significantly impact NPCC protection systems currently classified as SPS Type 3.

Members of the ISO-RTO Standard Review Committee (SRC) participated in the discussion. See Item 6.5 above.

Mr. Zito concluded the RAS discussion by stating that NPCC would continue to provide comment and feedback to the SDT as the standard is developed in addition to assessing the standards impact on NPCC's existing SPS criteria (Directory#7).

9.1.4 Directory #9 and #10 Generator Verification (status of TFCO Review)

MOD-25-2 *Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power* has been approved by FERC and is enforceable on July 1st, 2016. NPCC has completed a preliminary comparison between the criteria in Directories #9 and #10 and the requirements in MOD-25-2. TFCO has requested that an ad-hoc working group (CO7) be established to review this comparison and to recommend whether or not the criteria in Directories #9 and #10 should be revised or retired in consideration of MOD-25-2.

9.1.5 Directory #4 System Protection Criteria (status of TFSP Review)

TFSP reviewing document in accordance with the NPCC Reliability Assessment Program (NRAP). TFSP considering comments from the first open process posting and anticipates a second posting of the document.

10.0 RSC Member Items of Interest

10.1 RSC Roster
Action Item: Call Alan McNaughton on requesting another person for Sector 2.

11.0 Standards Activity Post NERC BOT Approval

(Since last RSC Meeting)

11.1 NERC Filings to FERC
http://www.nerc.com/FilingsOrders/Pages/default.aspx

13.1 Compliance Analysis Reports (CARs)
http://www.nerc.com/pa/comp/Pages/Compliance-Analysis-Reports.aspx

13.1.1 There have not been any CARs posted since the last RSC meeting

This item to be removed.

14.0 NERC Items of Interest (Since last RSC Meeting)

14.1 Lessons Learned
http://www.nerc.com/pa/rrm/ea/Pages/Lessons-Learned.aspx

14.1.1 Two new Lessons Learned have been issued since the last RSC meeting.

14.2 Alerts
http://www.nerc.com/pa/rrm/bpsa/Pages/Alerts.aspx

14.2.1 There has been no new NERC Alert released since the last RSC meeting.

See Item 5.5 for Vegetation Management.

14.3 Five Year ERO Performance Assessment
Guy Zito requested to remove this topic for future RSC meetings. The members of RSC agreed.

15.0 Other Items of Interest

15.1 2015 Regional Entity Business Plans and Budgets

15.2 NPCC Compliance Committee (CC)

January 14th – Call	February 18th – Call	March 17-18th Meeting
April 15th – Call	May 13th – Call	May 19-21st Workshop
June 16-17th Meeting	July 15th – Call	August 19th – Call
September 22-23rd Meeting	October 14th – Call	November 10-12th Workshop
December 3-4th Meeting		

15.3 NPCC Board of Directors Meeting (BOD)

February 3rd-4th Meeting	March 25th – Call	April 29th Meeting
June 4th – Call	June 25th Meeting	August 5th - Call
September 8th-9th Meeting	October 28th – Call	December 2nd Meeting

16.0 Future RSC Meetings and Conference Calls

16.1 RSC 2015 Meeting Dates

February 18th-19th, 2015 NextEra Energy Offices, Juno Beach FL
April 22th & 23th, 2015 Dominion Offices, Richmond VA
June 23rd & 24th, Saratoga NY
October 7th & 8th, Montreal Quebec

December 3rd & 4th, Albany NY

16.2 RSC 2015 Conference Call Schedule (calls can be scheduled as needed)
all Calls are planned to start at 10:00 a.m. (call: 415-655-0003 (USA) / 416-915-6530 (Canada), Guest Code 29086775)

January 16	January 30	February 13
March 6	March 20	April 2
May 1	May 15	May 29
June 12	July 10	July 23
August 14	August 28	September 11
September 25	October 23	November 6
November 20	December 18	

The meeting adjourned at 10:17a.m. Thursday April 23, 2015.

Respectfully Submitted,

Guy V. Zito, Chair RSC
Assistant Vice President-Standards
Northeast Power Coordinating Council, Inc.

Northeast Power Coordinating Council, Inc. (NPCC)

Antitrust Compliance Guidelines

It is NPCC's policy and practice to obey the antitrust laws and to avoid all conduct that unreasonably restrains competition. The antitrust laws make it important that meeting participants avoid discussion of topics that could result in charges of anti-competitive behavior, including: restraint of trade and conspiracies to monopolize, unfair or deceptive business acts or practices, price discrimination, division of markets, allocation of production, imposition of boycotts, exclusive dealing arrangements, and any other activity that unreasonably restrains competition.

It is the responsibility of every NPCC participant and employee who may in any way affect NPCC's compliance with the antitrust laws to carry out this commitment.

Participants in NPCC activities (including those participating in its committees, task forces and subgroups) should refrain from discussing the following throughout any meeting or during any breaks (including NPCC meetings, conference calls and informal discussions):

- Industry-related topics considered sensitive or market intelligence in nature that are outside of their committee's scope or assignment, or the published agenda for the meeting;
- Their company's prices for products or services, or prices charged by their competitors;
- Costs, discounts, terms of sale, profit margins or anything else that might affect prices;
- The resale prices their customers should charge for products they sell them;
- Allocating markets, customers, territories or products with their competitors;
- Limiting production;
- Whether or not to deal with any company; and
- Any competitively sensitive information concerning their company or a competitor.

Any decisions or actions by NPCC as a result of such meetings will only be taken in the interest of promoting and maintaining the reliability and adequacy of the bulk power system.

Any NPCC meeting participant or employee who is uncertain about the legal ramifications of a particular course of conduct or who has doubts or concerns about whether NPCC's antitrust compliance policy is implicated in any situation should call NPCC's Secretary, Ruta Skučas, Esq. at 1-202-470-6428.

NERC Reliability Standard Audit Worksheet (RSAW) Executive Tracking Summary

Revised: **6/5/2015**

ding the individual documents may be found at:
http://www.nerc.com/pa/comp/Pages/Reliability-Standard-Audit-Worksheets-(RSAWs).aspx

RSAW#	Title	Posted for Comment?	RSAW Issued?	Comments
BAL-001-1	Real Power Balancing Control Performance	x	3/28/2014	New RSAW Posted
BAL-002-02	Contingency Reserve for Recovery from Balancing Contingency Event	Yes (Thru 3/16/15)	1/29/2015	Revised RSAWs Posted
BAL-003-1	Frequency Response and Bias Settings - redline of prior version	x	1/21/2015	Draft RSAW Posted
BAL-005-0.2b	Automatic Generation Control	x	5/20/2013	Revised RSAWs Posted
CIP-001-2a	Sabotage Reporting	x	10/13/2012	
CIP-002-5.1	Cyber Security - BES Cyber System Categorization	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-003-6	Cyber Security - Security Management Controls	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-004-6	Cyber Security - Personnel & Training	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-005-5	Cyber Security - Electronic Security Perimeter(s)	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-006-6	Cyber Security - Physical Security of BES Cyber Systems	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-007-6	Cyber Security - System Security Management	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-008-5	Cyber Security - Incident Reporting and Response Planning	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-009-6	Cyber Security - Security Management Controls	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-010-2	Cyber Security - Configuration Change Management and Vulnerability Assessments	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-011-2	Cyber Security - Information Protection	Yes (Thru 4/14/15)	3/13/2015	Draft RSAW Posted
CIP-014-2	Physical Security	Yes (Thru 4/9/15)	2/20/2015	Draft RSAW Posted
COM-002-2a	Communication and Coordination	x	11/14/2012	
COM-002-4	Operating Personnel Communications Protocols	Yes (Thru 1/31/14)		
COM-003-1	Operating Personnel Communications Protocols	Yes (Thru 4/5/13)		
EOP-001-2.1b	Emergency Operations Planning	x	8/9/2013	Revised RSAWs Posted
EOP-002-3.1	Capacity and Energy Emergencies	x	3/20/2014	Revised RSAWs Posted
EOP-003-2	Load Shedding Plans	x	10/13/2012	
EOP-004-2	Event Reporting	N/A	10/15/2013	New RSAW
EOP-005-2	System Restoration from Blackstart Resources	x	7/17/2013	Revised RSAWs Posted
EOP-006-2	System Restoration Coordination	x	7/17/2013	Revised RSAWs Posted
EOP-008-1	Loss of Control Center Functionality	x	6/28/2013	Revised RSAWs Posted
EOP-011-1	Emergency Operations	Yes (Thru 9/25/14)	1-/20/2014	Draft RSAW Posted
FAC-001-2	Facility Interconnection Requirements	Yes (Thru 6/25/2014)		The draft RSAW is posted for feeback through June 25, 2014.
FAC-002-2	Facility Interconnection Studies	Yes (Thru 6/25/2014)		The draft RSAW is posted for feeback through June 25, 2014.
FAC-003-3	Transmission Vegetation Management	N/A	4/24/2014	Revision serves to clarify guidance for Requirement R6 regarding initial inspections for calendar year 2014 by expanding the Note to Auditor section
FAC-008-3	Facility Ratings	x	3/20/2014	Revised RSAWs Posted
FAC-013-2	Assessment of Transfer Capability for the Near-Term Transmission Planning Horizon	x	10/13/2012	
IRO-001-4	Reliability Coordination- Responsibilities	Yes (Thru 11/10/2014)	10/16/2014	Revised RSAWs Posted
IRO-002-2	Reliability Coordination - Facilities	x	3/20/2014	
IRO-002-4	Reliability Coordination - Monitoring and Analysis	Yes (Thru 11/10/2014)	10/16/2014	Revised RSAWs Posted
IRO-003-2	Reliability Coordination - Wide-Area View	x	3/20/2014	
IRO-005-3.1a	Reliability Coordination - Current-Day Operations	x	5/20/2013	Revised RSAWs Posted
IRO-008-2	Reliability Coordinator Operational Analyses and Real-time Assessments	Yes (Thru 12/22/2014)	11/5/2014	Revised RSAWs Posted
IRO-009-2	Reliability Coordinator Actions to Operate Within IROLs	Yes (Thru 7/8/2015)	3/16/2015	Draft RSAW Posted
IRO-010-2	Reliability Coordinator Data Specification and Collection	Yes (Thru 11/10/2014)	10/16/2014	Revised RSAWs Posted
IRO-014-1	Procedures, Processes, or Plans to Support Coordination Between Reliability Coordinators	x	10/13/2012	

RSAW#	Title	Posted for Comment?	RSAW Issued?	Comments
IRO-014-3	Coordination Among Reliability Coordinators	Yes (Thru 11/10/2014)	10/16/2014	Revised RSAWs Posted
IRO-017-1	Outage Coordination	Yes (Thru 11/10/2014)	10/16/2014	Revised RSAWs Posted
MOD-028-2	Area Interchange Methodology	N/A	10/10/2013	New RSAW
MOD-031-1	Demand and Energy Data	Yes (Thru 11/22/13)		Draft RSAW posted along with Draft Standard
NUC-001-2		N/A	4/24/2014	Revised RSAW represent the initial release for the errata versions of the Reliability Standard
PER-001-0.2	Operating Personnel Responsibility and Authority	x	5/20/2013	Revised RSAWs Posted
PER-003-1	Operating Personnel Credentials	x	1/23/2013	
PER-005-1	System Personnel Training	N/A	10/15/2013	Revised RSAWs Posted
PRC-001-3	System Protection Coordination	Yes (Thru 5/15/15)	4/16/2015	Draft RSAW Posted
PRC-002-NPCC-01	Disturbance Monitoring	Yes (Thru 10/21/2014)	9/19/2014	Revised RSAWs Posted
PRC-004-2.1a	Analysis and Mitigation of Transmission and Generation Protection System Misoperations	x	3/28/2014	Revised RSAWs Posted
PRC-004-3	Protection System Misoperation Identification and Correction	Yes (Thru 3/19/14)		Draft RSAW posted along with Draft Standard
PRC-004-5	Protection System Misoperation Identification and Correction	Yes (Thru 4/7/15)	2/20/2015	Draft RSAW Posted
PRC-005-1.1b	Transmission and Generation Protection System Maintenance and Testing	x	3/28/2014	Revised RSAWs Posted
PRC-005-2	Protection System Maintenance - Edits from Comments Received	x	10/14/2014	Draft RSAW Posted
PRC-006-2	Automatic Underfrequency Load Shedding	Yes (Thru 10/8/14)	9/10/2014	Revised RSAWs Posted
PRC-010-1	Undervoltage Load Shedding	Yes (Thru 8/7/2014)		
PRC-010-2	Undervoltage Load Shedding	Yes (Thru 4/7/15)	2/20/2015	Draft RSAW Posted
PRC-023-2	Transmission Relay Loadability	N/A	10/10/2013	Revised RSAWs Posted
PRC-025-1	Generator Relay Loadability	Yes (Thru 3/11/13)		
PRC-026-1	Relay Peformance During Stable Power Swings	Yes (Thru 12/2/2014)	11/12/2014	Draft RSAW Posted
PRC-027-1	Coordination of Protection System Performance During Faults	Yes (Thru 5/15/15)	4/16/2015	Draft RSAW Posted
TOP-001-1a	Reliability Responsibilities and Authorities	x	5/20/2013	Revised RSAWs Posted
TOP-001-3	Transmission Operations	Yes (Thru 1/7/2015)	12/3/2014	Revised RSAWs Posted
TOP-002-2.1b	Normal Operations Planning	x	3/20/2014	Revised RSAWs Posted

NPCC Regional Reliability Standards Executive Tracking Summary

Revised: 4/9/2015

Further details regarding the individual documents may be found at: http://www.npcc.org/regStandards/UnderDev.aspx

Line No.	Regional Standard ID	Regional Reliability Standard Title	RSAR Posted?	Posted for Comment?	Posted For Ballot?	Industry Approved?	NPCC BOD Approved?	NERC BOT Approved?	Petitioned for FERC Approval?	FERC Approved	Comments	Project Status
1	BPS-501-NPCC-01	Classification of Bulk Power System Elements (Withdrawn by RSC 8/07/09)	Yes (Thru 2/4/08)	NA	NA	NA	NA	NA	NA	NA	Withdrawn by RSC 8/07/09	Withdrawn
2	PRC-002-NPCC-01	Disturbance Monitoring	Yes (Thru 9/10/08)	Yes (Thru 10/24/09)	Yes (Thru 1/6/10)	Yes (1/6/10)	Yes (1/9/10)	Yes (11/4/10)	Yes (5/31/11)	Yes (10/20/11)	10/24/11 - Approved Standard posted publicly	Completed
3	PRC-006-NPCC-01	Automatic Underfrequency Load Shedding Program	Yes (Thru 8/25/08)	Yes (Thru 11/2/11)	Yes (Pre-ballot Thru 11/2/11)	Yes (11/18/11)	Yes (11/30/11)	Yes (2/9/12)	Yes (5/4/12)	Yes (2/21/13)		Completed
4	PRC-006-NPCC-02	Automatic Underfrequency Load Shedding										Under Development
5	PRC-002-NPCC-02	Disturbance Monitoring	Yes (Thru 2/23/2015)								Regional Standard Authorization Request (RSAR) has been submitted and approved Drafting Team Nomination period ended April 10, 2015	Under Development
6	PRC-002-NPCC-01, Interpretation R1.1		x	x	x	Yes (TFSP 10/19/12)	N/A	N/A	N/A	N/A	Posted on the NPCC website under "Regional Standards General" on 6/24/13	Completed
7	PRC-002-NPCC-01, Interpretation R1.2.2		x	x	x	Yes (TFSP 4/8/13)	N/A	N/A	N/A	N/A	Posted on the NPCC website under "Regional Standards General" on 6/24/13	Completed
7	PRC-002-NPCC-01, Interpretation R4, R5, and R6		x	x	x	Yes (TFSP 5/16/13)	N/A	N/A	N/A	N/A	Posted on the NPCC website under "Regional Standards General" on 6/24/13	Completed
9	BAL-002-NPCC-01	Regional Reserve Sharing	Yes (Thru 11/2/10)	Yes (Thru 12/16/11)	Yes (Thru 1/6/10)						Nomination Form posted - nominations due by 11/10/11	Under Development
10	PRC-012-NPCC-01	Special Protection Systems	Yes (thru 8/18/08)									On Hold
11	Regional Standard Processes Manual	Regional Standard Processes Manual (RSPM)	N/A	Yes (Thru 10/20/13)	Yes (Thru 1/27/14)	Yes (1/27/14)	Yes (3/11/14)				NERC posted the proposed NPCC Regional Standard Processes Manual for a 45-day industry review through 8 p.m. Eastern on Wednesday, May 7, 2014

NPCC Directory Executive Tracking Summary

Revised: 6/18/2015 Further details regarding the individual documents may be found at:

Line No.	Document	Developed From	Title of Directory	Responsible Task Force	Latest Version	Comments	Status
1	Directory #1	Criteria A-2	Design and Operation of the Bulk Power System	TFCP	Dec-09	CP11/CO7 Reviewing Phase 2 Draft	Directory#1 currently posted to the Open Process for a 3rd posting. Pending the resolution of further non substantive comments anticipate presenting Directory#1 and an implementation plan to the RCC in September. (Implementation Plan developed to install a 2nd line of high speed protection on certain facilities in New England).
2	Directory #2	Criteria A-3	Emergency Operations	TFCO	Jun-09		
3	Directory #3	Criteria A-4	Maintenance Criteria for Bulk Power System Protection	TFSP	Jun-09		Directory#3 retired effective April 1st, 2015 coinciding with nthe enforcement date of PRC -005-2.
4	Directory #4	Criteria A-5	Bulk Power System Protection Criteria	TFSP	Dec-09	TFSP reviewing D#4 in accordance with NRAP review.	Directory#4 currently posted to the Open Process by TFSP for a 2nd posting.
5	Directory #5	Criteria A-6	Reserve	TFCO	Oct-12		
6	Directory #6		Regional Reserve Sharing		Apr-12		
7	Directory #7	Criteria A-11	Special Protection Systems	TFSP	Jul-13		Task Force review underway to determine compliance implications for new defintion of RAS and revised PRC -012.
8	Directory #8	Criteria A-12	System Restoration	TFCO	Oct-10	TFCO working group CO11 reviewing initial Phase 2 draft of Directory #8.	TFCO Working Group CO11 reviewing Directory#8 to consider whether any of the battery testing in PRC -005-2 is dupicative with the battery testing in D8 for the Basic Minimum Power System.
9	Directory #9	Criteria A-13	Verification of Generator Gross and Net Real Power Capability	TFCO	Dec-11		TFCO has considered an initial review of the criteria in D#9 and D#10 to insure that it is not inconsistent with MOD-25-2. TFCO agreed to establish a Working Group to consider this issue. (MOD-25-2 is enforceable on 7/1/2016).
10	Directory #10	Criteria A-14	Verification of Generator Gross and Net Reactive Power Capability	TFCO	Dec-11		
11	Directory #12		Under frequency Load Shedding Program Requirements	TFSS	Jul-13		
12	Directory Manual		Directory Development and Revision Manual	N/A	Dec-13		On October 6th, 2014 the RSC approved revisions to the Directory Manual which incorporated cost considerations into the development of new or revised criteria as mandated by the NPCC BOD.

NPCC Directory Criteria Clarifications

Revised: **4/10/2015** Further details regarding the individual documents may be found at: https://www.npcc.org/Standards/Directory%20Interpretations/Forms/Public%20List.aspx

Line No.	Document	Title of Directory	Date Final	Task Force Review	Posted Open Process?	RCC Approval	Comments	Status
1	Directory #8 Interpretation	System Restoration	6/18/2012	TFCO	N/A	N/A	Interpretation on behalf of the NYSRC	Complete
2	Directory#3 Interpretation	Maintenance Criteria for Bulk Power System Protection	8/28/2012	TFSP	N/A	N/A	Interpretation on behalf of Bangor Hydro	Complete
3	Directory #3 Interpretation	Maintenance Criteria for Bulk Power System Protection	12/14/2012	TFSP	N/A	N/A	Interpretation on behalf of Con Ed	Complete
4	Directory #3 Interpretation	Maintenance Criteria for Bulk Power System Protection	2/15/2013	TFSP	N/A	N/A	Response Clarified - Interpretation on behalf of Acumen Engineered Solutions	Complete
5	Directory#3 Interpretation	Maintenance Criteria for Bulk Power System Protection	10/25/2013	TFSP	N/A	N/A	Interpretation on behalf of Hydro One Networks	Complete
6	Directory#3 Interpretation	Maintenance Criteria for Bulk Power System Protection	3/4/2015	TFSP	Yes on October 16th, 2014.	Yes	Interpretation on behalf of IESO-MACD	Complete.
7	Directory#8 Interpretation	System Restoration	Pending	TFCO	Pending	Pending	Interpretation on behalf of OPG.	CO11 has rendered the interpretation which will be posted to the Open Process to receive comments.

Quarterly Application to the Nova Scotia Utility and Review Board (NSUARB) for Approval of NPCC Regional Reliability Criteria

Revised: **6/17/2015**

Line No.	Filing Period	Filing Due	Filing Submitted	Comments
1	October 1 to December 31, 2012	3/1/2013	3/1/2013	This filing is NPCC's initial quarterly filing covering the October 1 to December 31, 2012 period and covers the changes to the NPCC Criteria as a result of voting by the Full Members of NPCC.
2	January 1 to March 31, 2013	6/1/2013	N/A	No changes were made during the refeenced period which required filing.
3	April 1 to June 30, 2013	9/1/2013	N/A	No changes were made during the referenced period which required filing.
4	July 1 to September 30, 2013	12/1/2013	11/25/2013	Revisions to D#7 and D#12 approved by the Full Members on 7/9/2013.
5	October 1 to December 31, 2013	3/1/2014	N/A	No changes were made during the referenced period which required filing.
6	January 1 to March 31, 2014	6/1/2014	N/A	No changes were made during the referenced period which required filing.
7	April 1 to June 30, 2014	9/1/2014	N/A	No changes were made during the referenced period which required filing.
8	July 1 to September 30, 2014	12/1/2014	N/A	No changes were made during the referenced period which required filing.
9	October 1 to December 31, 2014	3/1/2015	2/23/2015	(1) 10/15/14 NPCC Full Members approved retirement of D#3 effective 4/01/15 coinciding with enforcement date of PRC -005-2.
10		3/1/2015	N/A	(2) 10/6/14 the RSC approved revisions to the Directory Manual which incorporated cost considerations into the Manual.
11	January 1st to March 31st 2015	6/1/2015	N/A	No changes were made during the referenced period which required filing.
12	April 1st to June 30th 2015	9/1/2015	N/A	No changes were made during the referenced period which required filing.

Milestone Keys:

Tracking Spreadsheet: 2015 Project Work Plan (Status Updated: 3/

SP- SAR Posting
IB- Initial Ballot
AB - Additional Ballot
PB- Presented to BOT
F-Projected filing with FERC
PRP- Periodic Review Posting
PRR - Periodic Review Recommendation to SC

Project Status

No Issues with Project
Project Off Schedule by One Quarter
Project Off Schedule by Two or more Quarters
No Development Work in Progress

This worksheet displays estimates of anticipated standards development milestones for projects in 2015, and it is intended to be a project management tool for use in tracking the status of projects under development compared to their anticipated milestones. Detailed information for each project is available from their respective project pages on the NERC website. Projects that remained from 2014's Project Tracking Spreadsheet that were not prioritized in the RSDP, but that are continuing beyond the first quarter of 2015, are also represented here. Projects not anticipated to continue beyond the first quarter of 2015 are not included

Projected Posting Schedule

The above is a link to the schedule of upcoming postings, which is updated

Note 1: The prioritizations here reflect those prioritizations assigned as part of the 2015-2017 Reliability Standards Development Plan (RSDP). In its approach to prioritizing Reliability Standards projects, the RSDP considered how Reliability Standard family priorities are applied to individual projects and outstanding work. Specific elements included: (1) RISC Category Rankings; (2) regulatory directives; (3) regulatory deadlines; (4) Reliability Standard requirement candidates for retirement; (5) the IERP content and quality assessments; and (6) additional considerations (fill-in-the-blank status and five-year assessment commitments). Some projects were not prioritized in the RSDP, as they were originally anticipated to be

Note 2: Refers to guidances from regulatory orders for standards activity to consider, but that

Note 3: In the columns at right, in some cases, an "additional ballot" is not indicated for planning purposes, but if consensus is not supported on an initial ballot, or if substantive

Note 4: In the columns at right, there are no "plan" milestones in some cases because the project was originally planned to be complete in 2014, and the project's "actual" milestones

Note 5: In the column labeled "directionally consistent with IERP findings," directionally consistent indicates whether the Standard Drafting Team, when the project is completed, considered the recommendations from the Independent Expert Review Project and the Paragraph 81 project. After the Standard Drafting Team has considered the

Projected Posting Schedule

Below is a schedule of upcoming postings so you have the opportunity to schedule time with appropriate subject matter experts in your organizations to review these standards and ensure that balloters will be available during the ballot windows or have assigned proxies. The projected schedule is subject to change. For a high-level view of the planned schedule for all active projects, including information regarding the number of paragraph 81 requirements, directives, and guidances, please see the Project Tracking Spreadsheet on the Standards page.

Week of June 1:

- None

Week of June 8: **(Pending SC authorization June 10)*

- 2007-17.4 PRC-005 FERC Order No. 803 Directive Revised Informal posting (30-day informal comment period)*
  - Posting includes – revised SAR, redlined Standard, and implementation plan
- 2014-01 Standards Applicability for Dispersed Generation Resources White Paper (30-day comment period*)*
- 2015-04 Alignment of NERC Glossary of Terms and Definitions Used in the Rules of Procedures (Appendix 2 of the Rules of Procedure) (45-day comment period and Initial Ballot)*
- 2015-07 COM-001 FERC Order No. 808 Directive (14-day nomination solicitation)*
- 2015-07 COM-001 FERC Order No. 808 Directive Standard Authorization Request (SAR) (30-day comment period)*

Weeks of June 15: **(Pending SC authorization June 10)*

- 2015-08 PRC-006-3 Automatic Underfrequency Load Shedding – Variance for the Quebec Interconnection (14-day nomination solicitation)*
- 2015-08 PRC-006-3 Automatic Underfrequency Load Shedding – Variance for the Quebec Interconnection Standard Authorization Request (SAR) (30-day comment period)*

CIP V5 Transition Program FAQs Posted: NERC has posted a new group of FAQs to the CIP V5 Transition Program web page for industry comment. NERC will review all comments provided and incorporate changes before issuing a final version of the May 1, 2015 FAQs.	Type comments directly into the draft FAQ document as instructed in the document and submit the feedback to TransitionProgram@nerc.net.	05/01/15	06/15/15
First Draft of 2016 Business Plans and Budgets Posted for Review and Comment: NERC has posted the first drafts of its 2016 Business Plan and Budget and the Regional Entities' 2016 Business Plans and Budgets for review and comment. NERC has also posted a cover letter from Senior Vice President and Chief Financial and Administrative Officer Mike Walker and a PowerPoint presentation providing a summary and overview of the consolidated posting.	Submit comments to anya.josephson@nerc.net.	05/19/15	06/30/15

GENERAL STANDARDS NEWS

NEW Updated Archived Reliability Standards Under Development Web Page

NERC has updated the Archived Reliability Standards Under Development web page to include the projects listed in the Standard and Project Cross References guide located on the left navigation pane of the Standards web page. The Archived Reliaiblity Standards Under Development page provides a quick reference for closed projects. NERC updates it each time the NERC Board of Trustees adopts a new standard(s).

Solicitation Period Open for Supplemental Drafting Team Nominations for Project 2010-14.2.2 – Phase 2 of BARC: Time Error Correction

NERC is seeking nominations for the Project 2010-14.2.2 – Phase 2 of Balancing Authority Reliability-based Controls: Time Error Correction standard drafting team through 8 p.m. Eastern on June 1, 2015. Previous drafting or review team experience is beneficial but not required. A

brief description of the desired qualifications and expected commitment, along with Word and electronic versions of the nomination form, are available on the Standard Drafting Team Vacancies web page.

This is a supplemental solicitation to the initial solicitation held in March. At its May 20, 2015 meeting, the Standards Committee approved the nominations of the recommended nominees from the initial solicitation and requested that a supplemental nomination period be opened to garner additional team members. If you submitted a nomination form during the initial solicitation, please do not resubmit your nomination form, as you have already been selected for the drafting team.

New Resource for VRF and VSL Information

The former Violation Risk Factor and Violation Severity Level matrices were replaced by a single combined VRF and VSL report. The new Excel report includes categories for VRF, VSL, Jurisdiction, and Requirement. Each column is sortable with a separate worksheet for each category that provides additional information. The report will be updated each time a standard's VRF or VSL status changes, and a "Last Updated Date" column will indicate recent changes.

GENERAL COMPLIANCE AND ENFORCEMENT NEWS

NEW Upcoming Small Group Advisory Sessions

Continuing the series of advisory sessions that began earlier this year, the ERO is hosting three additional Small Group Advisory Sessions to provide helpful information to registered entities that are implementing the CIP Version 5 Reliability Standards:

- July 8–10, 2015 at Texas RE in Austin
- August 4–6, 2015 at NERC HQ in Atlanta
- September 1–3, 2015 at NERC HQ in Atlanta

QUICK LINKS

Risk-Based CMEP (RAI Page)
CIP V5 Transition Program
Risk-Based Registration Initiative
Reliability Standard Audit Worksheets
Enforcement & Mitigation: Enforcement Actions
Navigating Enforcement Data: Webinar & Presentation

Each session will be a closed one- to two-hour discussion between a registered entity's subject matter experts and ERO staff on issues pertinent to the entity's implementation of CIP V5. There is no limit to the number of entity subject matter experts who can participate, and NERC can arrange remote participation for those not attending in person.

NERC will schedule specific sessions and notify entities of their appointment times after reviewing the registration requests, which will be accepted on a first-come, first-served basis. If the number of requests exceeds the time allotted, NERC will make alternative arrangements for the affected entities.

NERC will not host a CIP V5 workshop in conjunction with these events; however, recordings of past workshops and other CIP V5 information is available in the Curriculum document on the CIP V5 Transition Program web page.

Registration links and other detailed event information for the Small Group Advisory Sessions are available below, under "Upcoming Events."

NEW Resources Posted for Latest Risk Elements Webinar

The slide presentation and recording from the Risk Elements Webinar Series: Monitoring and Situational Awareness on May 21, 2015 have been posted. Registration information for other upcoming webinars in the Risk Elements Webinar Series is available below, under "Upcoming Events."

OTHER NEWS

NEW State of Reliability Report Released

NERC completed an independent review of bulk power system trends to analyze the state of reliability and provide an integrated view of reliability performance in its annual *State of Reliability 2015*. The report's key findings show the bulk power system sustained high reliability performance, realized a reduction in unplanned transmission outages leading to load loss, maintained stable frequency response, and experienced no instances of load loss due to a cyber or physical security risk. Consistent with prior *State of Reliability* report findings, uncontrollable severe weather events continue to be the largest factor affecting the performance of the bulk power system.

The *State of Reliability 2015* report's findings and recommendations serve as input to NERC's risk assessment and reliability standards project prioritization of specific actions that can be taken to manage potential risks and enhance bulk power system reliability.

STANDARDS SUBJECT TO FUTURE ENFORCEMENT

The following standards are subject to future enforcement. Please refer to the U.S. Enforcement Dates page for more detail:

U.S. Enforcement Date	Standard(s)
July 1, 2015	MOD-032-1 – Data for Power System Modeling and Analysis; PRC-006-NPCC-1 – Automatic Underfrequency Load Shedding
October 1, 2015	CIP-014-1 – Physical Security; PRC-006-2 – Automatic Underfrequency Load Shedding; COM-001-2 – Communications
January 1, 2016	FAC-001-2 – Facility Interconnection Requirements; FAC-002-2 – Facility Interconnection Studies; NUC-001-3 – Nuclear Plant Interface Coordination
April 1, 2016	CIP-002-5.1 – Cyber Security – BES Cyber System Categorization; CIP-003-5 – Cyber Security – Security Management Controls; CIP-004-5.1 – Cyber Security – Personnel & Training; CIP-005-5 – Cyber Security – Electronic Security Perimeter(s); CIP-006-5 – Cyber Security – Physical Security of BES Cyber Systems; CIP-007-5 – Cyber Security – System Security Management; CIP-008-5 – Cyber Security – Incident Reporting and Response Planning; CIP-009-5 – Cyber Security – Recovery Plans for BES Cyber Systems; CIP-10-1 – Cyber Security – Configuration Change Management and Vulnerability Assessments; CIP-011-1 – Cyber Security – Information Protection; PRC-005-3 – Protection System and Automatic Reclosing Maintenance
July 1, 2016	BAL-001-2 – Real Power Balancing Control Performance; COM-002-4 – Operating Personnel Communications Protocols; MOD-025-2 – Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability; MOD-031-1 – Demand and Energy Data; PER-005-2 – Operations Personnel Training; PRC-019-1 – Coordination of Generating Unit or Plant Capabilities, Voltage Regulating Controls, and Protection; PRC-024-1 – Generator Frequency and Voltage Protective Relay Settings
July 1, 2017	MOD-033-1 – Steady-State and Dynamic System Model Validation

BOARD OF TRUSTEES AND FERC ACTION

There is no Board of Trustees or FERC action to report from last week.

UPCOMING EVENTS

For information about other NERC events, such as meetings and conference calls for standard drafting teams, other standing committees, subcommittees, task forces, and working groups, please refer to the NERC calendar.

Workshops and Conferences

- Project 2009-02 – Real-time Monitoring and Analysis Capabilities SAR Technical Conference – June 4, 2015, Atlanta | Agenda | Register to Attend in Person | Register to Attend via Webinar
- CIP Version 5 Small Group Advisory Sessions – July 8–10, 2015, Austin | Register by June 26| Texas RE Office Information

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Standards Authorization Request Form

When completed, please email this form to:
sarcomm@nerc.com

NERC welcomes suggestions to improve the reliability of the bulk power system through improved Reliability Standards. Please use this form to submit your request to propose a new or a revision to a NERC Reliability Standard.

Request to propose a new or a revision to a Reliability Standard			
Title of Proposed Standard:	PRC-006-3--Automatic Underfrequency Load Shedding – Variance for the Quebec Interconnection		
Date Submitted:	May 6, 2015		
SAR Requester Information			
Name:	Patrick Doyle Lee R. Pedowicz		
Organization:	Hydro-Québec TransÉnergie Northeast Power Coordinating Council, Inc. (NPCC)		
Telephone:	1-514-879-4100 ext 5429 1-212-840-1070	Email:	doyle.patrick@hydro.qc.ca lpedowicz@npcc.org
SAR Type (Check as many as applicable)			
☐ New Standard ☒ Revision to Existing Standard		☐ Withdrawal of Existing Standard ☐ Urgent Action	

SAR Information
Industry Need (What is the industry problem this request is trying to solve?):
The industry need for this SAR is to address two specific problems regarding UFLS requirements for the Quebec Interconnection : 1 - To meet the PRC-006-2 59.3 Hz requirement for scenarios where Quebec has a small generation

SAR Information
deficiency (between 4 and 6 percent) those scenarios would require modifications to the current settings of the UFLS program to the threshold of 59.3 Hz which would cause unacceptable and frequent load shedding without any improvement to System reliability. 2 – Because the Quebec Interconnection itself is an island with unique generation characteristics and SPS applications, Section D.A.3 in PRC-006-2 needs to be revised to define a more accurate generation deficiency scenario applicable to the Quebec Interconnection.
Purpose or Goal (How does this request propose to address the problem described above?):
The purpose of this SAR is to address the two problems mentioned above by modifying only those sections that are specific to the Quebec Interconnection (PRC-006-2 Section D. Regional Variances, Part D.A. Regional Variance for the Quebec Interconnection, and Attachment 1A (Quebec)). Revisions to the standard will ensure the continuity of System reliability in the Quebec Interconnection.
Identify the Objectives of the proposed standard's requirements (What specific reliability deliverables are required to achieve the goal?):
The modifications proposed in this SAR will not change the original goals and objectives of PRC-006-2 and will only affect the Quebec Interconnection.
Brief Description (Provide a paragraph that describes the scope of this standard action.)
A description of the two specific problems is as follows: 1 - The Quebec Interconnection has a low inertia compared to other Interconnections. This makes it subject to large frequency deviations during normal operation. Small generation deficiencies (4 to 6 percent) can lead to acceptable frequency deviations without triggering any UFLS thresholds, but still stabilize under a PRC-006-2 Attachment 1A performance curve. The scope of this SAR is to modify the performance curve in Attachment 1A to better reflect the design, performance, and modeling of the Quebec Interconnection and avoid unnecessary load shedding. 2 - The Quebec Interconnection is an island by itself and is the only island considered when performing the Quebec UFLS program assessment. No under-generated island can be created within the Quebec Interconnection. Under current planning and operational criteria, the largest generation deficiency scenarios are limited to the loss of the largest power plant not covered by a SPS. Using the peak case scenario, these generation deficiencies are far from the required 25%. Section D.A.3 should be revised to account for the characteristics of the Quebec Interconnection.

SAR Information
Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR. Also provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)
1 - Because of the characteristics of the Quebec Interconnection, 0.5-1.5 Hz frequency deviations resulting from small losses of generation occur frequently. The System is designed and operated such that these small generation losses are acceptable, do not pose any threat to System reliability, and do not lead to unnecessary automatic load shedding. The adjustment of the UFLS anti-stall threshold to meet the PRC-006-2 performance curve would cause frequent and unacceptable load shedding operations without any improvement to System reliability. This is clearly shown by recent UFLS program assessment studies, planning and operational studies, and the analysis of generation loss scenarios in the Quebec Interconnection. During the 2014 assessment of the NPCC Underfrequency Load Shedding Program, studies showed that for small generation deficiencies (between 4 and 6 percent) in the Quebec Interconnection using the minimum spinning reserve requirement, the simulated frequency deviation does not meet the PRC-006-2 requirement of 59.3 Hz from Attachment 1A. However, further investigation determined that such scenarios result in acceptable frequency deviations without crossing any UFLS thresholds while stabilizing between the PRC-006-2 curve (59.3 Hz in Attachment 1A) and the upper UFLS (anti-stall) threshold (59.0 Hz) that is defined in PRC-006-NPCC-1 UFLS Table 4 - Quebec Interconnection. Meeting the PRC-006-2 59.3 Hz requirement for those scenarios would require modifications to the current settings of the UFLS program. The subsequent adjustment of the UFLS anti-stall threshold to 59.3 Hz would cause unacceptable and frequent load shedding without any gain to System reliability. 2 - The Quebec Interconnection is an island by itself and it is the only island considered when performing the Quebec UFLS program assessment. Due to the nature of the Quebec System's design (main generation centers located in the north, remote from the main load centers in the south), no other viable island with generating deficiencies can be created within the Quebec Interconnection. Under current planning and operational criteria, the largest generation deficiency scenarios are limited to the loss of the largest power plant not covered by a SPS. Assuming the Hydro-Quebec peak case scenarios, none of them would result in a 25% generation deficiency. To reach the 25 % criteria using a design (normal or extreme) contingency and viable island, a light load scenario was used while studying the loss of the largest power plant. This methodology is currently used in Hydro-Quebec and has been

SAR Information
used since the JWG-2 Phase II (NPCC Joint Working Group for the review of adequacy of procedures for protection against off-nominal frequency operation) Report was published in 1993. However, further studies and investigations have shown that using the peak case scenario, the integrity of the Quebec Interconnection could not be preserved using a UFLS program for a 25% generation deficiency. Since there is no design contingency that can produce a generation deficiency of 25%, multiple extreme contingencies, such as the loss of more than one substation, need to be applied simultaneously on the peak case scenario in order to reach that level of generation deficiency. Using the peak load case scenario, these generation deficiencies do not meet the required 25%. Section D.A.3 should be revised to reflect the characteristics of the Quebec Interconnection.

Reliability Functions	
The Standard will Apply to the Following Functions (Check each one that applies.)	
☐ Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐ Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐ Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒ Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐ Resource Planner	Develops a one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐ Transmission Planner	Develops a one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐ Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).

Reliability Functions		
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☒	Distribution Provider	Delivers electrical energy to the end-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the end-use customer.

Reliability and Market Interface Principles	
Applicable Reliability Principles (Check all that apply).	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☒	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☒	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Reliability and Market Interface Principles	
Does the proposed Standard comply with all of the following Market Interface Principles?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

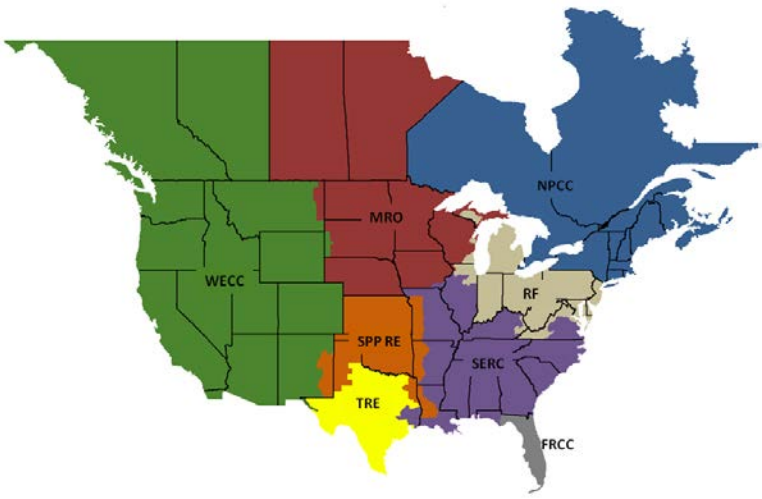
Preface

This document is a work in progress. The executive summary, annexes, definitions of terms, abbreviations, and rosters may be modified prior to final publication. The final report will also include the incorporation of additional formatting, as well as other checks on abbreviation, references in footnotes, grammar, etc. All figures will also be properly cleaned and formatted for clarity, based on the mock-ups included in this draft. Figures and tables have not yet been numbered or referenced in the text. The data and conclusions in this document are subject to change until the report is finalized and submitted to the NERC Planning Committee (PC) for approval.

The North American Electric Reliability Corporation (NERC) is a not-for-profit international regulatory authority whose mission is to assure the reliability of the bulk power system (BPS) in North America. NERC develops and enforces Reliability Standards; annually assesses seasonal and long-term reliability; monitors the BPS through system awareness; and educates, trains, and certifies industry personnel. NERC's area of responsibility spans the continental United States, Canada, and the northern portion of Baja California, Mexico. NERC is the electric reliability organization (ERO) for North America, subject to oversight by the Federal Energy Regulatory Commission (FERC) and governmental authorities in Canada. NERC's jurisdiction includes users, owners, and operators of the BPS, which serves more than 334 million people.

The North American BPS is divided into several assessment areas within the eight Regional Entity (RE) boundaries, as shown in the map and corresponding table below.



FRCC	Florida Reliability Coordinating Council
MRO	Midwest Reliability Organization
NPCC	Northeast Power Coordinating Council
RF	ReliabilityFirst
SERC	SERC Reliability Corporation
SPP-RE	Southwest Power Pool Regional Entity
TRE	Texas Reliability Entity
WECC	Western Electricity Coordinating Council

Executive Summary

This report summarizes the 12 tasks performed by the Integration of Variable Generation Task Force (IVGTF). The IVGTF's objective is to evaluate the effects of large-scale integration of variable generation (VG) and identify the long-term reliability considerations needed to ensure the reliability of the BPS. The findings and recommendations from the multi-task effort provide a reference of best practices and considerations for planners, operators, and regulators, with recommendations identifying areas that require further development. Areas of improvement are suggested for technical considerations, additions to regional requirements or guidelines, and Standards Authorization Requests (SARs) for new or enhanced Reliability Standards.

NERC's *2013 Long-Term Reliability Assessment* noted that renewable capacity (including wind, solar, hydro, biomass, and geothermal) will grow by approximately 55 GW by 2023. With over 35 GW of planned nameplate capacity, wind accounts for over half (64 percent) of these additions.[1] Anticipating substantial growth of VG, NERC's Planning Committee (PC) and Operating Committee (OC) created the IVGTF that first prepared the 2009 overview report entitled *Accommodating High Levels of Variable Generation*.[2] In addition to defining various technical considerations for integrating high levels of VG, the IVGTF report identified a work plan of follow-on tasks to investigate potential mitigating actions, practices, and requirements needed to ensure BPS reliability. The 12 reports that are summarized herein represent the results of the follow-on tasks that were identified in the initial 2009 report.

The purpose of this report is to document all recommendations from the task force and determine the status of these recommendations by identifying next steps for NERC. While this is an ongoing process, the task force members recognize that various recommendations have already been addressed by standard drafting teams, other task forces or working groups, and in NERC's special reliability assessment reports since the reports were published. Therefore, IVGTF leadership, in collaboration with NERC's System Analysis and Data Modeling group and selected NERC standard drafting teams, and members from Essential Reliability Services Task Force (ERSTF) has reviewed the recommendations from all the reports to determine the appropriate actions. Appendix I contains an *IVGTF Transition Plan* that identifies the next steps for the IVGTF recommendations, including recommendations that are still relevant for possible revisions to standards, additions to technical guidelines, suggestions for further research, or recommendations for operating and planning best practices.

[2] NERC, *Special Report - Accommodating High Levels of Variable Generation*, http://www.nerc.com/files/IVGTF_Report_041609.pdf, April 2009.

Background and Recommendations Summary

North America is facing a significant growth in VG resources over the coming 10 years, making it necessary to reliably integrate these resources into the grid. Continued integration of VG was identified among long-term reliability challenges in the *2013 Long-Term Reliability Assessment,* where nameplate renewable capacity (including wind, solar, hydro, biomass, and geothermal) is projected to grow by approximately 55 GW by 2023. With over 35 GW of planned nameplate capacity, wind accounts for 64 percent of these additions. Driven in large part by new policies and environmental priorities, this growth will create one of the largest resource integration efforts in the history of the electric industry.

In addition to defining various technical considerations for integrating high levels of VG, the PC and OC's IVGTF report identified a work plan of follow-on tasks to investigate potential mitigating actions, practices, and requirements needed to ensure BPS reliability. Table 1 illustrates all IVGTF objectives and their associated special assessment reports prepared by different drafting teams.

Table 1: IVGTF Task Force Topics and Objectives

IVGTF	Objective(s)	Special Assessment
Task 1-1	Identify the need for Modeling, Data and Analysis (MOD) standards.	Standard Models for Variable Generation May, 2010
	Determine valid, generic, non-confidential, and public power flow and stability models for VG technologies.	
	Review existing NERC MOD standards.	
Task 1-2	Address consistent and accurate methods to calculate capacity values attributable to VG.	Methods to Model and Calculate Capacity Contributions of Variable Generation for Resource Adequacy Planning March, 2011
Task 1-3	Make recommendations for how NERC interconnection procedures and standards should be enhanced to address: • Voltage and frequency ride-through • Reactive and real power control • Frequency and inertial response criteria	Interconnection Requirements for Variable Generation September, 2012
Task 1-4	Develop the planning and operational practices as well as the methods and resources needed to integrate VG resources into the BPS.	Flexibility Requirements and Metrics for Variable Generation: Implications for Planning Studies August, 2010
Task 1-5	Identify the need to assess reliability implications of integrating:	Potential Reliability Impacts of Emerging Flexible Resources

	• Plug-in hybrid electric vehicles • Storage Devices • Demand Response (DR) programs	November, 2010
Task 1-6	Summarize the potential influence on power system operating and planning decision problems of VG increased uncertainty.	Probabilistic Methods July, 2014
	Describe the role that probabilistic methods can play in improving the basis on which the various decisions are made.	
Task 1-7	Discuss potential requirements for Variable Energy Resources (VERs) connected to distribution facilities, and the potential BPS reliability impacts if VERs do not remain interconnected, stable, and operational during and after normally expected momentary system disturbances in the BES, and offer general guidelines of Voltage Ride Through (VRT) and Frequency Ride Through (FRT) specifications for distributed VERs for consideration in the IEEE 1547 Standard revision.	Performance of Distributed Energy Resources During and After System Disturbance Voltage and Frequency Ride-Through Requirements December, 2013
Task 1-8	Identify the potential impacts of Distributed Energy Resources (DERs).	Potential Bulk System Reliability Impacts of Distributed Resources August, 2011
	Identify potential mitigating strategies.	
	Review existing NERC Registry Criteria specific to DER applications.	
	Propose potential future approaches to ensure continued reliability in systems with large amounts of DERs.	
Task 2-1	Discuss the forecasting requirements for the 48 hours of operation ahead and how forecasting information can be delivered to the system operator in a useful and actionable way.	Variable Generation Power Forecasting for Operations May, 2010
Task 2-2	Address communications requirements between the variable renewable generation plant and the Balancing Authority (BA).	Reliability Considerations for BA Communications with Increased Variable Generation March, 2012
Task 2-3	Assess the need for and requisite participation in the acquisition of ancillary services.	

	Study provisions of ancillary services from other jurisdictions, ACE sharing, or shorter scheduling intervals within and between BA Areas to manage and spread the effects from variability of generation resources over a larger footprint.	Ancillary Services and Balancing Authority Area Solutions to Integrating Variable Generation March, 2011
	Review existing and proposed standards.	
Task 2-4	Discuss VG impact on power system operations.	Operating Practices, Procedures and Tools March, 2011
	Discuss the need to modify operating practices, procedures, and tools.	
	Address the impacts on commitment and/or dispatch along with reserve management practices.	

Main Recommendations and Key Findings

This report summarizes one of the most important issues facing the reliability of the BPS today—the large-scale integration of VG. In light of the increasing long-term VG trend and as a result of the accomplishments of the 12 IVGTF task reports, addressing the effects of VG on the reliability of the BPS will require significant changes to traditional methods used for system planning and operation. The reports represent broad industry consensus and a pioneering IVGTF effort to lay the foundation for the reliable integration of VG into the BPS. This summary report highlights areas of recommendations where further study, enhanced practices, modifications to existing standards, suggestions for consideration of new standards, and ongoing coordination with the industry are needed to ensure reliability as more VG resources are added to the grid.

Findings and recommendations from the IVGTF multi-task effort provide a reference manual of best practices for planners, operators, regulators, developers, and investors dealing with the challenges and opportunities offered by VG. Therefore, this summary report identifies recommendations into the following categories:

- Modeling, Data and Analysis (MOD) Standards Development and Reconciliation
- VG for Resource Adequacy In Operation and Planning
- Interconnection Requirements
- Flexibility Requirements
- Reactive Power and Voltage Control Requirements
- Active Power Control Capabilities
- Disturbance Requirements
- Communications Requirements
- Harmonics and Subsynchronous Interaction
- VG Power Forecasting
- Ancillary Services Requirements

The report also provides a status update through a constructive transition plan for all recommendations from all 12 of the task reports according to appropriate next phases of considerations and actions. Table 2 highlights the main recommendations and their associated transition categories, which fall into the following categories:

- Standards Review and/or Standard Authorization Request (SAR)
- Enhancements to Modeling
- Definition – Revisions or Addition by NERC
- Operating – Technical Guidelines
- Planning – Technical Guidelines
- Research and Development
- NERC Training and Education
- NERC Reliability Assessments
- Operators Training and Data Collection
- Essential Reliability Services Task Force (ERSTF)
- NERC Staff/External Coordination Activity
- No Action:
  - No Action – Recommendation is out of scope.
  - No Action – Recommendation is not applicable (e.g., due to market or commercial action improvements).
  - No Action – Recommendation is completed or has been addressed by different projects.

The most important recommendations are those that target a gap or enhancements needed to NERC Reliability Standards. The IVGTF has highlighted three key areas that should be addressed by a new NERC Reliability Standard or enhancement of an existing Reliability Standard. Those are:

- **Interconnection Requirements**
  - FAC-001 needs to be clarified to state that interconnection standards for reactive power must cover specifications for minimum static and dynamic reactive power requirements at full power and at partial power. The requirement should include how terminal voltage affects the power factor or reactive range requirement.
  - Consider modifying VAR-001 to include the term “plant-level volt/var controller” (in addition to “AVR”), which is more appropriate for VG.
- **Reactive Power and Voltage Control Requirements**
  - Create a clear definition of acceptable control performance for minimum reactive power capability requirements for interconnection of all generators.
  - Add applicability recommendations for generator interconnection requirement for reactive power
  - Include specification of reactive range defined over the full output range and applicable at the point of connection
  - Specify expected reactive control performance, including minimum control response time for voltage control, power factor control, and reactive power control.
- **Active Power Control Capabilities**
  - NERC should investigate variable generating plants at an active power level where dynamic reactive capability is limited or zero.

- NERC should specify active power requirement during a voltage disturbance unless there is a reliability concern (review of PRC-024 standards and clarity on repeated disturbances).
- NERC should include active power curtailment capabilities of various types of generation as one of the possible remedies available to Balancing Authorities (review EOP-002 and add clarity on Control Performance and Disturbance Control Standards).

- **Variable Generation Forecasting Requirements**
  - Add forecastingMOD information available for VG for next-day system studies (review IRO-004 Reliability Coordination – Current-Day Operations and add VG forecasting information to provide an accurate day-ahead study).
  - Include active monitoring of forecasting conditions such as weather fronts, icing, and high-wind conditions by the Reliability Coordinator (review IRO-005 Reliability Coordination – Current-Day Operations).
  - Include a section about forecasting, identifying the data submitted by variable generators as the method of providing generation information to the Transmission Operators, and also recognizing forecasting as the best way to estimate generation, albeit subject to some unavoidable uncertainty due to the variability and complexity of weather conditions. This would assist in system operations, especially in day-ahead or hour-ahead operations (review TOP-006 Normal Operations Planning).
  - Include specific tools, such as (1) input from a forecaster, and (2) real-time data from wind and solar plants (e.g., meteorological towers, sonic detection and ranging (SODAR) and real-time turbine telemetry) (review TOP-006 Monitoring System Conditions).
  - NERC Reliability Standards that address the reasonable and effective use of regional forecasts and local wind/solar facility forecasts should be encouraged and used to schedule VG to assist in accurate system operation. Wind plant output forecasts, often several of them, should be adopted as standard system and market operation tools for economic operation and system reliability purposes. Ramp forecasts and hourly energy forecasts should be considered.

More details, including the specific transition category for each IVGTF recommendation, can be found in Appendix I of this report.

Lastly, the Conclusions and Recommendations section of this report provides a perspective on the significance of the work in the context of ongoing system evolution.

Table 2: Main Recommendation Topics Covered by Task Forces' Work Plan Activities

Recommendation Category	Recommendations	Transition Category
MOD Standards Development and Reconciliation	Provide sufficient clarity to model VG.	Enhancements to Modeling
	Support simulation of power system with high amounts of VG aiming to incorporate VG considerations in the next release of the MOD standards.	No Action – Completed

VG for Resource Adequacy in Operation and Planning	Resource adequacy models (e.g., LOLP models) that reflect the much lower availability or lower load-carrying capability of VG.	Planning – Technical Guidelines
	Measure VG performance factors such as capacity factors and peak coincidence.	Research & Development
	Apply more research using probabilistic methods for reserve calculations, dispatch, unit commitment, maintenance, generation, and transmission planning.	Research & Development
Interconnection Requirements	Consider adding a clarification to FAC-001 expanding R.2.1.3 or as an appendix, stating that interconnection standards for reactive power must cover specifications for minimum static and dynamic reactive power requirements at full power and at partial power. Include how terminal voltage should affect the power factor or reactive range requirement (see Section 2.8.3 for technical guidelines).	Standards Review and/or SAR
	Consider modifying VAR-001 to include the term "plant-level volt/var controller" (in addition to "AVR"), which is more appropriate for VG.	Standards Review and/or SAR
	Enhance models for facility interconnections studies—consideration for MOD 24 to MOD 27 enhancements.	No Action – Completed
	Detailed dynamic (and possibly transient) models for the specific equipment may be needed for the System Impact Study and Facilities Study to represent the facility and other equipment in the electrical vicinity.	Enhancements to Modeling
	Support simulation of power system with high amounts of VG.	Planning – Technical Guidelines
	Review DER interconnection standards.	No Action – Completed[3]
	Investigate interconnections for breaker requirements.	Planning – Technical Guidelines
Flexibility Requirements	Probabilistic planning methods being developed in NERC's IVGTF Task 1-6 will be a vital improvement to assess required flexibility.	Research & Development
	Set of best planning practices to design systems with sufficient system flexibility to accommodate targeted levels of VG should be documented.	Planning – Technical Guidelines

[3] IEEE Standard 1547 full revision effort is underway. NERC, tasks 1-3 and 1-7 team addressing disturbance ride-through requirements are participating in this effort in addition to national lab, some consultants, EPRI, solar developers, inverter manufactures, NREL and some utility representatives from the distribution side. NERC encourages BES reliability experts from utilities and ISOs to participate.

	Develop and collect metrics that measure flexibility needs for VG. For example, calculating a set of ramp and intensity metrics can provide insights on flexibility trends.	ERSTF
	The electric power industry should pursue research and development activities to assess the flexibility needs for the regional and interregional systems of North America as well as evaluate the benefits of flexible resources and technologies (i.e., DR, electric and thermal energy storage, and plug-in electric vehicles (PEVs)) on their respective systems.	Research & Development
	Advances and enhancements that inform all resources of the value of needed flexibility services and incent desired response while discouraging undesired response will be needed (e.g., a tariff for PEV owners that would discourages charging during peak hours and encourages charging during off-peak hours).	NERC Training & Education
	Maintenance scheduling may be more difficult in market regions where there is limited central authority to coordinate scheduled maintenance, and high levels of VG will likely have a significant influence. Methods to quantify the risk of both capacity shortfalls and flexibility shortfalls can be developed and tested in industry.	Planning – Technical Guidelines
	Generation planning: New methods have been developed to begin quantifying flexibility needs and risks of insufficient flexibility within generation expansion planning algorithms so that results balance investment in VG with investments in technologies providing the flexibility that VG requires.	Planning – Technical Guidelines
	The IVGTF suggests that those Balancing Areas that face significant integration of variable resources consider studying the benefits of sub-hourly scheduling to manage the integration of VG. Depending on the current or projected BA system characteristics, assuming sufficient transmission is available, there may be benefits to intra-hour interchange scheduling in the form of reduced ancillary services and more flexibility and ability to manage the variability, while still meeting the requirements of NERC's Reliability Standards.	ERSTF
Reactive Power & Voltage Control Requirements	NERC should promote greater uniformity and clarity of reactive power requirements contained in connection standards.	
		No Action
	NERC should consider initiating a SAR to establish minimum reactive power capability standards for the interconnection of	Standards Review and/or SAR

	all generators, and provide clear definitions of acceptable control performance.	
	Review applicability recommendations for generator interconnection requirement for reactive power.	Standards Review and/or SAR
	Review specification of Reactive Range defined over the full output range, and it should be applicable at the point of connection.	Standards Review and/or SAR
	Review and clarify MOD-025-1 Verification of Generator Gross and Net Reactive Power Capability, recommendation.	No Action – Completed
	Definition of Control Performance: Expected volt/var control performance should be specified, including minimum control response time for voltage control, power factor control, and reactive power control. An interim period for the application of precisely defined control capabilities should be considered.	Standards Review and/or SAR
Active Power Control Capabilities	NERC should investigate variable generating plants at an active power level where dynamic reactive capability is limited or zero.	Standards Review and/or SAR
	Include active power requirement during a voltage disturbance unless there is a reliability concern – PRC-024 standards.	Standards Review and/or SAR
	Require VG curtailment capability.	Operating – Technical Guidelines
	VG plants should be required to have the capability to limit the rate of power increase.	Planning – Technical Guidelines
	Plants must be able to accept commands to enable pre-selected ramp-rate limits.	Planning – Technical Guidelines
	Encourage or mandate the reduction of active power in response to high frequencies.	Planning – Technical Guidelines
	Consider requiring the capability to provide an increase of active power for low frequencies.	Planning – Technical Guidelines
	Summarize requirements of facility connection model grid code requirements: tests shall be performed (power ramping and power curtailment).	Enhancement to Modeling
Disturbance Requirements	In the short term, NERC should engage in current efforts to revise DER interconnection standards by providing information, supporting the efforts of IEEE with transmission reliability subject matter experts, raising industry, regulator,	NERC Staff

	and policy maker awareness, and encouraging the consideration of the explicit VRT and FRT for DERs.	
	The initial focus should be on potential ways to adopt minimum-tolerance thresholds for VRT and FRT in IEEE Standard 1547 while balancing against other important distribution issues such as safety and protection/coordination.	NERC Staff
	The task force also offers general guidelines on VRT and FRT specifications for distributed VERs and other DERs, for consideration in the P1547a process or future IEEE Standard 1547 revisions.	NERC Staff
	Provide guidelines to generator frequency and voltage protective relay settings.	Planning – Technical Guidelines
	Apply Control performance and disturbance control requirements.	No Action
Communications Requirements	Provide communications guidelines between VG plants and grid operators.	Operating – Technical Guidelines
	Technical Developments: Development of an operational infrastructure that provides visibility and control (direct or indirect) of distributed resources such as DR and PEVs.	Operating – Technical Guidelines
	For the Industry: Wind and solar plants require real-time meteorological and electrical data through SCADA systems using standard communication protocols for use in forecasting and system operation, including power, availability, curtailment, and meteorological data.	Operating – Technical Guidelines
	For the Standards: Review COM-002 (Communication and Coordination).	No Action – Completed
	Communication Recommendations for Wind Resources: Data and communication capabilities should be provided to the BA by all generation operating in the BA. Wind and solar plants should have the capability to send and receive real-time data (meteorological and electrical) through SCADA systems.	Operating – Technical Guidelines
Data Collections	NERC should design and implement a way to collect high-quality VG data that would help inform calculations of capacity value.	NERC Staff
	Design study reports that assess the harmonic performance of all wind and solar plants.	Research and Development

Harmonics and Subsynchronous Interaction	Provide a technical guidelines document to 1) understand the control interactions, 2) assessing the risk, and 3) if necessary mitigation of wind and solar plants located near series-compensated transmission lines or HVDC terminals.	Operating – Technical Guidelines
VG Power Forecasting	Use wind forecast error models and the forecast in unit commitment.	Operating – Technical Guidelines
	Standards revisions: FAC-001: Facility Connection Requirements	Operating – Technical Guidelines
	Standards revisions: TOP-002-2.1b: Normal Operations Planning	No Action
	Standards revisions: TOP-006-2: Monitoring System Conditions	No Action
	Standards revisions: BAL-002-1: Disturbance Control Performance	ERSTF
	Standards revisions: COM-002-2: Communications and Coordination	No Action
	Standards revisions: IRO-005-3.1a: Reliability Coordination – Current-Day Operation	No Action
Ancillary Services Requirements	Each Region or reserve-sharing group should permit contingency reserve deployment under imbalance energy circumstances.	Operating – Technical Guidelines
	The task team recommends that the generator interconnection requirements be modified to require this dispatchable control capability interface.	Operating – Technical Guidelines
	Regional market operators and other grid operating entities should develop the ability to consider transmission service by prioritizing variable resources when allocating curtailment responsibility to variable output resources during reliability-limited operating conditions.	Operating – Technical Guidelines
	Depending on the current or projected BA system characteristics, assuming sufficient transmission is available, use intra-hour interchange scheduling to increase the benefits in the form of reduced ancillary services, more flexibility and ability to manage the variability, while still meeting the requirements of NERC's Reliability Standards.	Operating – Technical Guidelines

Task 1-1: Standards Models for Variable Generation

Task 1-1 focused on the identified need for standard, generic, non-confidential, and publicly available power flow and stability models for VG technologies and for a task force to review existing NERC Modeling, Data and Analysis (MOD) standards to ensure high levels of VG can be simulated and appropriately addressed through the existing standards. Task 1-1 provided, at the time the report was issued, a detailed discussion of model and model validation in general, followed by an account of the current status of models for various VG technologies. It then provides a discussion of the relevant NERC MOD standards and where they will need to be augmented to properly address VG.

The Task 1-1 report[4] identified a need to have models that are standard (i.e., a defined model structure used by all commercial software tools), publicly available, and not specific to any particular design (i.e., "generic" and able to reasonably represent key performance relevant to BPS studies). Following the issuing of the report, much work has been done in the industry such as the release of a second generation of generic models[5] that have resulted in significant progress in meeting the needs identified in the Task 1-1 report. These models are now available in several commercial power system simulation software platforms used in North America.

The Task 1-1 report provides an overview of the models and modeling capability available at the time of issuing the report. Gaps and areas requiring further work were identified. As mentioned above, some of these gaps have since seen progress, while others are still being worked on. The modeling and model development discussed is primarily for power system power flow, short circuit, and stability analysis.

The report also addresses NERC modeling standards and recommended improvements. The regional model building manuals developed as part of MOD-11 and MOD-13 must provide sufficient clarity to model VG. These manuals may ask for best available models or generic models. The models cover the operational time frame and the 10-year planning horizon. The manuals do not currently cover the frequency for revalidating model data. While not included in the standards, more emphasis is currently being placed on meeting the Eastern Interconnection Reliability Assessment Group (ERAG) model of building manual requirements in addition to regional requirements. Specific recommendations are included for each of the MOD standards.

Key Findings and Recommendations

Annual NERC Model Development Process

It is important that the regional model building manuals developed as part of MOD-11 and MOD-13 provide sufficient clarity to model VG. These manuals may ask for best available models or generic models. These models cover the operational time frame and the 10-year planning horizon. The manuals do not currently cover the frequency for revalidating model data.

NERC Standards

The NERC Glossary of Terms would benefit from the inclusion of the term "Variable Generation." A possible definition was included in the Phase I report of the IVGTF.

[4] NERC Special Report on *Standard Models for Variable Generation*.
http://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/Standards%20Models%20for%20Variable%20Generation.pdf
[5] Specification of the Second Generation Generic Models for Wind Turbine Generators, WECC Report approved 1/23/14
https://www.wecc.biz/Reliability/WECC%20Second%20Generation%20Wind%20Turbine%20Models%20012314.pdf.

Table 3: IVGTF Recommended Standards Improvements		
Standard	**Definition**	**Recommendations**
MOD-011	Regional Steady-State Data Requirements and Reporting Procedures	Apply VG as a source of generation.
MOD-013-1	RRO Dynamics Data Requirements and Reporting Procedures	Include an explicit statement to cover VG.
MOD-024-1	Verification and Data Reporting of Generator Real Power Capability	Require wind units' total gross capability methods as the sum of the nameplate rating of all individuals.
MOD-025-1	Verification of Generator Gross and Net Reactive Power Capability	Clarification may be needed. Namely, VG reactive capability of the "power plant" is not entirely inherent in the individual generating units regarding how the total reactive capability of the power plant is defined.
MOD-026-1	Verification of Models and Data for Generator Excitation System Functions – SECOND POSTING	Standards are tailored explicitly to deal with synchronous-type generators, and items need to be clarified in these standards as they pertain to VG, particularly for: • Unit/plant size for validation • Validation of various technologies in a single plant • Validation of different control layers • Modeling and model validation • Future functionality • Modeling of protection • Issues related to the fuel source for VG model revalidation The latest versions of MOD 26 and 27 address these issues based on the above recommendations made in 2010.
MOD-27	Verification of Models and Data for Turbine/Governor and Load Control	
FAC-001	Facility Connection Requirements	NERC Reliability Standard FAC-001-1 should be expanded to clearly cover modeling requirements during the coordinated joint study phase of the Facility connection process. Simple generic models of VG may be adequate for the IES phase, and more detailed models may be needed for the IFS phase. Validation of the simple and detailed model parameters may be needed during commissioning.

Task 1-2: Methods to Model and Calculate Capacity Contributions of VG for Resource Adequacy Planning

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Methods to Model and Calculate Capacity Contributions of Variable Generation for Resource Adequacy Planning.	Address consistent and accurate methods to calculate capacity values attributable to VG.	Michael Milligan March, 2011

Task 1-2 addresses consistent and accurate methods to calculate capacity values attributable to VG, including:

1. Technical considerations for integrating variable resources into the BPS.
2. Specific actions, practices, and requirements, including enhancements to existing or development of new Reliability Standards:
    a. Calculations and metrics, including definitions and their applications used to determine capacity contribution and reserve adequacy.
    b. Contribution of VG to system capacity for high-risk hours, estimating resource contribution using historical data.
    c. Probabilistic planning techniques and approaches needed to support study of BPS designs to accommodate large amounts of VG.

System planners require consistent and accurate methods to calculate the capacity contribution that can be attributed to VG to ensure the adequacy and stability of the bulk power grid. Long-term historical data sets allow for characterization and trending of key performance metrics, including those factors that contribute to resource availability and adequacy. VG, like wind and solar, does not have long-term historical data sets, and this lack of data limits the understanding of the long-term implications of VG performance. The potential output levels of VG show a large degree of variance over a wide geographic scale, so the ideal type and capacity contribution of VG will differ by location. Task 1-2 discusses the known characteristics of regional VG along with the current practices used by systems planners to predict VG output potential and capacity contribution during peak-demand hours to ensure grid reliability.

Key Observations

Comparison of reliability-based approaches used to calculate the effective load-carrying capability (ELCC) of VG is needed.

- LOLE Metric: The traditional approach is based on the Loss-of-Load Expectancy (LOLE) of 0.1 days/year as the reliability target. This approach considers only the peak hour of the days that have significant Loss-of Load-Probability (LOLP). This is typically a relatively small number of days because most of the year there is a surplus of capacity. A significant daily LOLE means that during the day there is some probability of insufficient generation, but the metric does not indicate the duration of the potential insufficiency, nor does it indicate the potential energy shortfall.
- LOLH Metric: A Loss of Load Hours (LOLH) metric considers all hours during which there may be a risk of insufficient generation. With high penetrations of VG, this may be an advantageous metric because of the variability of these resources. This provides a more accurate assessment of adequacy in the sense that all

hours are examined by the metric. However, unlike the daily LOLE, there is no generally accepted hourly target. Additional analysis is required to determine the relationship between LOLE and LOLH reliability targets.

It will be important to provide ongoing evaluation of the potential impacts of new VG resources on the grid.
VG is anticipated to increase substantially in the North American grid. Because prospective VG plants, by definition, do not already exist, obtaining data that can describe the likely behavior of future plants is critical for a number of reliability, adequacy, and integration tasks that are performed in the planning cycle. Because weather is the principle driver for load and for VG output, it is critical to maintain chronology between VG and load. Specific locations of future VG may not be known with certainty, and to evaluate the likely impacts, multiple scenarios may need to be evaluated. Because of these issues, it will be important to develop and maintain a public database of wind and solar estimated (future) production. Large-scale Numerical Weather Prediction (NWP) models or solar radiation and cloud cover models can be used to provide high-resolution wind power and solar power data. The value of this type of dataset has been shown in the Eastern Wind Integration and Transmission Study (EWITS) and the Western Wind and Solar Integration Study (WWSIS).

Industry education on metrics and calculation used for capacity contributions will provide a better outlook on the true nature of VG.
Based on the experience of many participants of the IVGTF Task Force 1-2, it seems apparent that the workings of LOLP, ELCC, and related reliability approaches are not always well understood. This highlights the need for the dissemination of information regarding the behavior and performance of these metrics.

The performance of VG should be tracked to understand the resource adequacy contributions of various technologies.
Calculating capacity value for existing VG sources requires chronological generation data that is synchronized with load data and other relevant system properties. Existing power system databases can be used to track this data, which would be useful in helping to better understand VG performance and operational issues (addressed by other work streams of the IVGTF). NERC already collects data to inform the GADS database. Although it is more data intensive than the GADS process, operational data from VG over the next several years will be extremely valuable in the assessment of capacity value and operational issues surrounding the use of VG.

Key Findings and Recommendations

The 1-2 report provides the reader with a general framework for determining the contributions and best use of VG in the bulk power grid. In order to ensure the proper allocation of the increase in VG, NERC suggests the following:

Metrics

- Additional research to compare traditional reliability targets (such as a LOLE of 0.1 day/year) to alternative metrics.
- LOLP, LOLE, or other related metrics should be used to calculate generation adequacy and capacity contributions of VG.
- **Planning reserve margin, calculated as a percentage of system peak, will become less meaningful with large penetrations of VG.**
- Industry to adopt more widely energy-related reliability metrics and targets as the share of VG increases in the power system; implement comparison of results based on these alternative metrics.

Multi-Area Reliability Adequacy

- Alternative approaches and assumptions regarding the treatment of interconnected systems should be transparent to the analysis.
- Development of one or more common approaches for addressing the impact of interconnected systems in the reliability assessments will be useful.

Alternative Approaches

- Planning reserve margin levels should be periodically benchmarked with, or derived from, an LOLP or related approach to resource adequacy to account for any changes.
- Simplified approaches should be benchmarked and calibrated to the rigorous ELCC calculations to ensure the validity of the approximation.
- The ramp response characteristic includes the rate of ramping required from flexible resources and the predictability of the ramp:
  - Measuring the maximum magnitude change over various time scales (e.g., 10 min., 30 min., 1 hr., and 4 hrs.), and unit start-up times would capture the rate-of-ramp aspect of ramp response.
  - Predictability needs to include components such as event forecast accuracy and advance warning.
- Study and validate resource adequacy approaches based on alternative study results comparisons.

Data Collection

In the time since the Task 1-2 report was written, there have been advances in modeling that now make it possible to do a good job of creating 5-minute data, which aligns better with how existing markets work. This would be a better match for analyses, not just because of Task 1-2, but also because of other production simulation modeling mentioned in this report.

- NERC should design and implement a way to collect data that would help inform calculations of capacity value.
- NERC should request that government agencies like the DOE, working with NOAA/NCAR and the resource assessment industry, develop annual high-resolution, modeled wind and solar power data on 10-minute time scales and 2 km or smaller geographic grids.

Education

- NERC should facilitate the dissemination of information about how LOLP-related reliability and adequacy calculations perform and what they measure.

Task 1-3: Interconnection Requirements for VG

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Interconnection Requirements for Variable Generation	Make recommendations for how NERC interconnection procedures and standards should be enhanced to address: • Voltage and frequency ride-through • Reactive and real power control • Frequency and inertial response criteria	Richard Piwko September, 2012

Task 1-3 addresses interconnection requirements for VG. Many of NERC's existing interconnection standards and procedures have been based on technical characteristics and physical capabilities of traditional power generation resources that employ synchronous generators. VG comprises any power generating facility where the source of the energy is not dispatchable. Wind and solar generation are the most common types of VG, though ongoing research may lead to increased utilization of tidal, wave, ocean thermal, and other resources. Some common characteristics of wind plants and solar photovoltaic (PV) plants include:

- The energy source is variable, influenced by atmospheric conditions, and predicted by day-ahead and short-term forecasting.
- VG plants are often comprised of multiple individual "generators" connected and operated in a coordinated manner.
- The power sources (such as wind turbines or solar panels) are connected to the electrical network via power electronics rather than synchronous generators.
- Responses to system disturbances are primarily determined by control functions, not the inherent electromechanical dynamics of synchronous generators.

Task 1-3 provides recommendations for how NERC interconnection procedures and standards should be enhanced to address voltage and frequency ride-through, reactive and real power control, and frequency and inertial response criteria, considering the evolving range of technical characteristics and physical capabilities of VG equipment.

Key Findings and Recommendations

1. Reactive Power and Voltage Control

Recommendations for Modification of Existing NERC Standards

NERC should consider revisions to the FAC and VAR standards to ensure that reactive power requirements for all generators are addressed in a technically clear and technology-neutral manner. As with all new or changing requirements, appropriate consideration should be given to the applicability to existing generators. Suggested updates are as follows:

- Consider adding a clarification to FAC-001 expanding R.2.1.3 or an appendix stating that interconnection standards for reactive power must cover specifications for minimum static and dynamic reactive power

requirements at full power and at partial power. Include how terminal voltage should affect the power factor or reactive range requirement (see Section 2.8.3 below for technical guidelines).

- Consider modifying VAR-001 to include the term "plant-level volt/var controller" (in addition to "AVR"), which is more appropriate for VG.

A large amount of VG, including most of the solar PV deployment, will be relatively small plants with capacity below the threshold specified in the existing NERC Registry Criteria, and connected at voltages below 100 kV. This includes residential and commercial systems, as well as larger plants connected to the distribution or sub-transmission system. To the extent that these systems, in aggregate, can affect the reliability of the BPS, the FAC and VAR standards should be extended or revised to govern them. A prospective NERC standard addressing reactive requirements for smaller plants should recognize that distribution-connected VG plants have traditionally been operated in power factor control mode.

General Recommendations for Standards Development and Reconciliation

For the most part, existing NERC and FERC interconnection standards were developed with synchronous generators in mind. As such, these standards do not fully define performance requirements for reactive power support. This has resulted in unclear, inconsistent, and sometimes inappropriate interconnection reactive power requirements for generators, especially VG. Specific recommendations are as follows:

- NERC should promote greater uniformity and clarity of reactive power requirements contained in connection standards that Transmission Operators have issued pursuant to FAC-001. NERC, FERC, and other applicable regional standards should be reconciled.
- NERC should consider initiating a SAR to establish minimum reactive power capability standards for interconnection of all generators and provide clear definitions of acceptable control performance.

Technical Guidelines for Specification of Reactive Power Requirements

VG technologies are technically capable of providing steady-state and dynamic reactive power support to the grid. Based on a review of best practices and operating experience, the report offers the following technical guidelines for specification of reactive power capability and control requirements for interconnection of generating plants to the transmission system:

- **Applicability:** The generator interconnection requirement for reactive power should be clearly established for all generator technologies. NERC should consider giving transmission planners some discretion for variance based on the characteristics of their transmission systems and the sizes of the generators.
- **Specification of Reactive Range:** The reactive range requirement should be defined over the full output range, and it should be applicable at the point of connection.
- **Impact of System Voltage on Reactive Power Capability:** It should be recognized that the system voltage level affects a generating plant's ability to deliver reactive power to the grid, as well as the power system's requirement for reactive support.
- **Specification of Dynamic Reactive Capability:** The standard should clearly define what is meant by "Dynamic" Reactive Capability by specifying the portion of the reactive power capability that is expected to be dynamic. A prospective standard should specify the minimum performance characteristics of the response in terms of response time, granularity (maximum step size), and repeatability (close-open-close cycling capability).
- **Definition of Control Performance:** Expected volt/var control performance should be specified, including minimum control response time for voltage control, power factor control, and reactive power control. An interim period for the application of precisely defined control capabilities should be considered.

- **Effect of Generator Synchronization on System Voltage:** Synchronization of generators to the grid should not cause excessive dynamic or steady-state voltage change at the point of connection. A 2 percent limit may be considered as a baseline.
- **Special Considerations:** NERC should investigate whether Transmission Operators can, under some conditions, allow variable generating plants to operate normally or temporarily at an active power level where dynamic reactive capability is limited or zero.
- **Technical Alternatives for Meeting Reactive Power Capability:** The reactive power requirements should be applicable at the point of interconnection.
- **Commissioning Tests:** Commissioning tests, which are part of the interconnection process, often include a test to demonstrate plant compliance with reactive power capability requirements.

2. Performance During and After Disturbances

Applicable Plants

The scope of PRC-024-1 should be broadened to cover smaller plant sizes. The current proposal of 75 MVA will miss many variable generator facilities that could impact the Bulk Electric System. The scope should be broadened to cover all projects under a Large Generator Interconnection Agreement (LGIA), or all projects greater than 20 MW. Another option is to extend the scope to any project greater than 10 MW in order to provide coverage for plants not included under IEEE 1547. This IVGTF task team could not come to a consensus on the exact plant threshold (10 vs. 20 MW or MVA). It is recommended that industry decide the appropriate threshold as Regional differences may be justified. Applicability should depend on total plant rating and should not be based on individual unit size.

3. Disturbance Ride-Through

Fault ride-through and frequency ride-through capability of generators will be covered by the NERC standards under development. TPL-001-2 will cover the planning assessment for new and existing generators to ensure that grid performance Reliability Standards are met. PRC-024-1 will provide additional clarity to the generator industry in terms of uniform requirements.[6] No additional requirements are needed for FAC-001-0.

Ride-through plots should be provided that specify both high- and low-voltage ride-through requirements. The zero-voltage ride-through should be equal to the three-phase fault-clearing time on the network. The zero-voltage ride-through is up to nine cycles but may be less depending on the clearing time. This should be made explicit in any requirement.

PRC-024 should clearly define performance requirements for unbalanced and balanced faults. The specification of voltage magnitude should define what voltage metric is applicable.

Voltage disturbance performance requirements, particularly high-voltage ride-through, should use the severity-cumulative duration form of specification to avoid unnecessary increase of VER plant costs to meet voltage disturbance durations that will never occur in practice.

It is not suggested that a NERC-wide requirement be mandated for riding through a rate-of-frequency change. If a standard is desired by individual operators, a rate-of-change ride-through requirement of 2.5 Hz/s appears

[6] Subsequent to the issuance of the Task 1-3 report the proposed Standard PRC-024 was changed to eliminate the voltage and frequency disturbance ride through requirements. The Task-1-3 report was based on a draft version of PRC-024 that would have required all new generators to ride-through voltage and frequency disturbances but that version was rejected by the NERC ballot body and the version that was adopted and accepted by the NERC board has no ride through requirements. The Task 1-3 recommendations might have been different had they been based on version of PRC-024 that was adopted in the spring of 2013.

adequate. (This rate of frequency change is stipulated in the current draft of PRC-024). There may be some regional differences where at least 4.0 Hz/s is required.

PRC-024 should define the performance required during and after disturbances and should make clear and unambiguous what remaining "connected" entails. It is not recommended that active power be required during a voltage disturbance unless there is a reliability concern. The sourcing of reactive power during a severe fault should instead be given priority over real power delivery, and the magnitude of reactive power should be consistent with pre-fault reactive power capability. The capability to supply reactive current during a fault varies with technology and product offerings, so a market to incentivize, but not require, the increased sourcing of reactive current during a voltage dip is recommended.

Disturbance performance requirements, including PRC-024, should indicate the maximum level of transmission contingency (e.g., N-1-1) that a plant should be required to ride through.

Disturbance performance requirements, such as PRC-024, should clearly define any requirement for repeated disturbances.

Transmission-interconnected VERs should not have any active anti-islanding functions enabled unless these functions are properly coordinated with all applicable stakeholders so that they do not detract from bulk transmission system transient or dynamic stability.

4. Power Recovery

It is not necessary to specify a detailed power recovery characteristic for variable generators in a standard. Detailed accurate models provided by the Generator Owner will be sufficient for interconnection studies. If performance criteria are not met, then the Transmission Owner/Planner can work with the Generator Owner to develop a mitigation plan.

Recovery after Blackout

It is reasonable to clarify the restart expectations of a generator facility following a disturbance. In some cases, the Transmission Operator provides a signal to the facility that prohibits automatic restarting after a severe grid event. FAC-001 could be modified to include a facility connection requirement to address generator facility restarting.

Standards for Manufactured Equipment

Current solar PV inverters designed to comply with IEEE 1547 are required to provide anti-islanding capability and disconnection requirements that are not compatible with the fault ride-through requirements recommended here. Although individual inverters may have capacities of the order of 500 kW, utility-scale PV plants may have hundreds of these units and hence have a plant capacity upwards of 100 MW. Furthermore, the inverters are listed according to UL-1741, which is based on the requirements of IEEE 1547. This report recommends that new standards be proposed for utility-scale PV plants in order to drive the industry toward the adoption of new inverter specifications, testing, and certification.

5. Active Power Control Capabilities

Require Curtailment Capability, but Avoid Requirements for Excessively Fast Response

VG can respond rapidly to instructions to reduce power output. In many cases, response is faster than conventional thermal or hydro generation. However, there have been cases where grid codes[7] have included

[7] The grid code specifies day-to-day procedures for both planning and operational purposes and covers both normal and exceptional circumstances. It is divided into a Planning Code, Connection Conditions, Operating Code, Balancing Code, Data Registration Code, and General Conditions. Detailed definitions can be found at the NERC website.

excessive requirements for speed of step response to a curtailment order. This is technically challenging and should be avoided. A change (Δ) of 10 percent (%)/s for rate of response to a step command to reduce power output is reasonable. This rate of response to step instructions should not be confused with the imposition of ramp-rate limits, as discussed next. Active power considerations are not driving reliability requirements at this time.

Some conventional generation can reach or even exceed these rates, but most cannot. The project team is not aware of any NERC standards that specify rate of response to re-dispatch commands (of which curtailment is a subset) in this time frame. Typically, plants must respond to economic re-dispatch within minutes. Mechanisms such as markets or other incentives to encourage rapid rate of response from all generating resources should be considered.

Require Capability to Limit Rate of Increase of Power Output

VG plants should be required to have the capability to limit the rate of power increase. This type of ramp-up rate control capability has been required in some systems. This function should include the ability to be enabled and disabled by instruction from the Transmission Operator, BA, or Reliability Coordinator. Plants must be able to accept commands to enable pre-selected ramp-rate limits. Plants should be designed with recognition that ramp-rate limits should not be required under all operating conditions. VG plants should not be required to limit power decreases due to declines in wind speed or solar irradiation (i.e., ramp down rate limits). However, limits on decreases in power output due to other reasons, including curtailment commands, shut-down sequences, and responses to market conditions, can be reasonably required.

Encourage or Mandate Reduction of Active Power in Response to High Frequencies

VG plants should be encouraged to provide over-frequency droop response of similar character to that of other synchronous machine governors.

Consider Requiring the Capability to Provide Increase of Active Power for Low Frequencies

This is the other side of frequency control. VG plants should not be required to provide governor-like frequency response for low frequency under normal operating conditions. This is consistent with any conventional power plant operating at full throttle output (i.e., valves wide open). However, encouraging VG plants to have the capability to provide this response, and then establishing rules and possibly compensation for when such controls would be enabled, could be considered. This presumably would be a rare occurrence, as the economic penalty associated with enabling these controls is high.

Consider Requiring Inertial Response in Near Future

Some manufacturers are now offering inertial response for wind turbines. This is distinct from the previous two items on frequency response in that inertial response is faster and strictly transient in nature. Consequently, there is not a significant economic penalty associated with the use of this new feature.

Synchronous generators have inherent inertial response. It is not a design requirement. It is simply a consequence of the physical characteristics of the rotating masses connected to a synchronous generator. With the exception of Hydro-Québec, inertial response characteristics have not been specified in grid codes or interconnection requirements for wind plants. Furthermore, language describing this functionality in technology-neutral terms and subject to the physical reality of VG facilities is not presently available.

Requiring this function in the future as the technology matures and as grid operators and reliability organizations learn more about the need for inertial response characteristics from wind plants should be evaluated further. However, incremental costs should be carefully weighed against alternatives on both the supply and demand side for providing this capability.

6. Harmonics and Subsynchronous Interaction

Although harmonics and subsynchronous interaction issues can pose a reliability risk to the power grid in some instances, such risks are rare and only affect a small portion of VG plants. There is no need for NERC to develop interconnection criteria related to sub-synchronous resonance (SSR)/subsynchronous interactions (SSI) or harmonics at this time. However, it would be prudent for Transmission Owners and grid operators to:

- Consider design study reports that assess the harmonic performance of all wind and solar plants; and
- Until better understanding of the control interactions issue is gained, consider design study reports that assess the risk and, if necessary, mitigation of wind and solar plants located near series-compensated transmission lines or HVDC terminals.

7. Models for Facility Interconnection Studies

Discussion of Generator Unit/Facility Size Applicability

Accurate models are required for all generator facilities that are connected to or are planning to connect to the Bulk Electric System (100 kV and higher) regardless of size. However, NERC's current Statement of Registry Criteria is the governing document that defines applicability of entities to NERC Reliability Standards.

Ongoing model revalidation is currently covered by:

- MOD-024-1: Verification of Generator Gross and Net Real Power Capability
- MOD-025-1: Verification of Generator Gross and Net Reactive Power Capability
- MOD-026-1: Verification of Models and Data for Generator Excitation System Functions
- MOD-027-1: Verification of Models and Data for Turbine/Governor and Load Control

These standards were reviewed and reported on in the NERC special report, *Standard Models for Variable Generation*.[8] The ongoing detailed model validation may evolve to cover generator units or generator facilities 75 MVA or larger. This breakpoint covers at least 80 percent of the currently installed generation in North America and matches the NERC Statement of Compliance Registry Criteria, which is approved by FERC.

Generator facilities smaller than the 75 MVA threshold—especially VG facilities—may experience rapid changes in control performance over their lifetimes due to equipment upgrades and replacements. These changes should be captured in updated models. However, substantial modifications on facilities less than 75 MVA may not be captured by the FAC-001 standard or MOD standards.

NERC Standard FAC-001-0 Modifications

Transmission Owners' and Transmission Operators' interconnection procedures are part of their respective Open Access Interconnection Tariffs, such as the FERC Large Generator Interconnection Procedures. NERC Reliability Standard FAC-001-1, Facility Connection Requirements, approved by the NERC Board of Trustees February 2012, addresses a number of issues related to FAC-001-0, including the applicability of FAC-001-1 to Generator Owners as well as Transmission Owners.

> *R3.1.17 Generation facility modeling data, including appropriate power flow, short circuit and dynamic models, and verification requirements.*

[8] Special Report – *Standard Models for Variable Generation*
http://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/Standards%20Models%20for%20Variable%20Generation.pdf

Modeling needs for the interconnection process are different than modeling needs for evaluation of regional grid performance. To clarify this point, we recommend that the following statement be added to the FAC-001-0 standard as an appendix for clarifying R3.1.17:

> "Preliminary or approximate power flow and dynamic models may be adequate for the preliminary assessment of interconnection impacts, or to represent existing and proposed projects that are not in the immediate electrical vicinity of the facility being studied. However, detailed dynamic (and possibly transient) models for the specific equipment may be needed for the System Impact Study and Facilities Study to represent the facility and other equipment in the electrical vicinity. Generic non-proprietary publicly available models are more appropriate for the NERC model building process covered by existing MOD standards, although validated generic models with specifically tuned parameters may be adequate for interconnection studies. The models for interconnection studies must be acceptable to the Transmission Owner in terms of simulation platform, usability, documentation and performance."

The above recommended sub-requirement R3.1.17, as with all of the sub-requirements in FAC-001-0, leaves it to the Transmission Owner to "fill in the blanks" or develop specific requirements that will be applied to facilities intending to interconnect to their network. This can lead to inconsistencies across the grid. In order to avoid inconsistencies, several facility interconnection requirement documents or grid codes were reviewed to try to develop a recommended best practice to aid Transmission Owners. A review of grid codes as of 2011 can be found in Appendix 5 of the Task 1-3 report. However, as mentioned previously, these grid codes are in a constant state of change.

Summary of Facility Connection Model Grid Code Requirements

After reviewing the interconnection procedures and standards of several grid codes with respect to models and model validation, several key features could be considered for adoption by Transmission Owners:

- Preliminary model data may be used for the initial feasibility study of a variable generator interconnection project.
- The best model available should be used for the final System Impact Study or Facilities Study. These models can be user written and require nondisclosure agreements.
- The detailed dynamic model must be accurate over the frequency range of 0.1 to 5 Hz. Time constants in the model should not be less than 5 ms.
- The detailed dynamics model must have been validated against a physical or type test.
- Verification of detailed model performance should be confirmed during commissioning to the extent possible. The following tests shall be performed:
  - primary/secondary voltage control
  - low-voltage and high-voltage ride-through
  - power factor/reactive power capability
  - power ramping and power curtailment
- Verification of non-proprietary model accuracy may be performed by simulation tests compared with the detailed model performance.
- At the end of the commissioning tests, the Generator Owner should provide a verified detailed model and a non-proprietary model, ideally in IEEE, IEC, or other approved format, for ongoing regional studies such as TPL-001.

8. Communications between Variable Generation Plants and Grid Operators

The Task 1-3 project team recommends that the basic requirements for communications and control between grid operators and VG plants be based on the existing policy for conventional generators.

- VG plants should send a minimum set of monitoring data to the grid operation via the SCADA network.
- VG plants should receive and execute command signals (power limit, voltage schedule, ramp-rate limit, etc.) sent from the grid operator via the SCADA network.
- VG plants should have trained on-call plant operators who can receive calls from the grid operator 24/7 and who can immediately execute verbal commands. The plant operators would not need to be located at the plant, provided they have secure remote control capability for the plant.

Task 1-4: Flexibility Requirements and Metrics for Variable Generation Implications for System Planning Studies

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Flexibility Requirements and Metrics for Variable Generation: Implications for Planning Studies	Develop the planning and operational practices as well as the methods and resources needed to integrate VG resources into the BPS.	Michael Milligan August, 2010

Task 1-4 focuses on the IVGTF work plan directive: *Resource adequacy and transmission planning approaches must consider needed system flexibility to accommodate the characteristics of variable resources as part of bulk power system design.* The NERC Planning Committee's Resource Issues Subcommittee should study changes required to current resource adequacy assessment processes to account for large-scale VG integration. Considerations should include ramping requirements, minimum generation levels, required shorter scheduling intervals, transmission interconnections, etc.

This report concentrates on how to assimilate or consider VG into resource and transmission planning. Data needs are identified and the report makes recommendations to responsible NERC entities. The goals of the report are to:

- Study resource and transmission planning process changes required to include VG characteristics; and
- Identify data requirements to support resource adequacy assessment and determine which NERC entities should collect, retain, and provide this data.

The Task 1-4 report documents the extent to which resource adequacy and transmission planning processes may need to consider system flexibility to accommodate the characteristics of variable resources as part of BPS design. Planning studies have historically concentrated on the concept of adequacy. Task Force 1-4 developed a study approach that will:

- Describe the characteristics of the net load to be served by conventional generation and the need for flexibility;
- Document the experience of power systems that already have a relatively high penetration of VG;
- Identify sources of flexibility;
- Discuss metrics that can be used to characterize flexibility;
- Discuss the tools required for system planning to include system flexibility and to present conclusions and recommendations.

This information will be used to determine how flexibility could be accounted for and measured in existing studies, whether flexibility should be accounted for differently in planning studies, and what kind of metrics could be needed to measure flexibility.

Historically, system planning studies generally have not explicitly addressed the need for system flexibility, as the characteristics and performance of conventional generating technologies included design requirements to meet

variability and randomness from demand, which is well understood and predictable. Power system variability was addressed in resource planning studies by identifying the most economic resource mix to meet a time-varying load profile. In transmission planning studies, it was addressed by evaluating loss of source in the local area. However, for reliable operation, adequate amounts of system flexibility are required to accommodate large amounts of VG. Without this flexibility, the penetration of VG may be limited to ensure the reliability of the BPS. Therefore, planning and design processes will need to change, depending on basic system characteristics, to provide the flexibility needed to meet targeted levels of VG. Development of appropriate flexibility metrics is an important aspect in facilitating these new processes.

The Task 1-4 report documents:

- How VG will increase the need for the power system to be able respond to increased variability;
- How power systems have begun to address the need for increased flexibility;
- A framework to measure flexibility; it concludes with how recent large-scale VG integration studies provide a framework for addressing flexibility in planning studies; and
- Recommendations as to how a set of best practices can be developed for modifying planning tools now to address flexibility, and how the state of the art for conducting system planning studies can be advanced to more effectively capture the need for increased flexibility.

Charting new ground is always challenging. The development of metrics for a multi-dimensional concept like power system flexibility and incorporating it into planning studies presents a significant challenge. This report provides a framework to accomplish that end and a foundation for future work.

As the penetration of VG increases, system flexibility requirements will also increase. This flexibility manifests itself in terms of the need for dispatchable resources to meet increased ramping and load following, some of which could occur rather unexpectedly (i.e., not forecast). This flexibility will need to be accounted for in system planning studies to ensure system reliability. Enhancements to existing system planning practices will be required to account for increased flexibility necessitated by the integration of VG. System planning studies focus both on the reliability of the power system as well as optimizing the overall economics of the power system; here, the emphasis is on reliability.

The primary data for assessing system flexibility requirements resulting from the integration of VG is the net load (load minus VG in all time frames). Currently, there is no universally accepted measure or index of flexibility that would facilitate comparison across systems. The availability of such an index could potentially facilitate the evaluation of flexibility.

Current system planning practices and tools with appropriate modifications and enhancements have provided a basis for evaluating the impact of VG on system flexibility needs. For example, net load impacts can be evaluated explicitly or implicitly with tools (such as a chronological production cost simulation model) that typically model hourly or sub-hourly operations and all relevant physical constraints, including minimum-generation-level ramp rates and transmission constraints. Since the task 1-4 report was written, advances have occurred in production simulation modeling (more granularity and better accuracy) to obtain five-minute models instead of hourly models, although hourly models are still useful. A number of recently completed studies with the objective of evaluating the integration of VG have successfully used these models. They include studies by the California ISO, the Ontario Power Authority, the Electric Reliability Council of Texas (ERCOT) and, more recently, the Department of Energy (*Eastern Wind and Transmission Integration Study*)[9]. All of the studies, to some extent, address how VG impacts the need for system flexibility. The studies collectively covered the following aspects:

[9] Department of Energy (DOE) Eastern Wind and Transmission Integration Study http://energy.gov/sites/prod/files/2013/12/f5/47078.pdf

- Production cost models, which includes transmission models to assess the interaction between the dispatchability of wind and transmission;
- Extensive use of statistical analysis of hourly and sub-hourly wind plant output and net-load data (mainly simulated but some historical data was used where available) to ensure that production cost models adequately capture ramp rate and minimum generation constraints and account for regulation requirements;
- Wind forecast error models to account for operational impacts caused by the uncertain nature of VG (wind forecasting is covered by Task 2-1); and
- Resource adequacy models (e.g., LOLP models) that reflect the much lower availability or lower load-carrying capability of VG (this topic is covered in detail by Task 1-2).

In addition, these studies identified data needs specific to incorporating VG into planning studies:

- Determination of the interconnection point for the VG
- Specification for and identification of data sources that facilitate the accurate modeling of VG resources.
- Models and associated data that enable the accurate simulation of the output of VG and ensure output profiles are contemporaneous with the load profile and represent the uncertainty in the profile
- Data needed to conduct both transient and voltage stability analysis for wind plants

Important planning topics, such as system stability analysis and transmission planning, are neglected by many of these studies but are recognized as important and in need of attention. In particular, the transmission planning that accounts for the flexibility needs is a topic that has hardly been addressed. For example, the more variable nature of power flows driven by the VG output may need to be addressed by the integrated transmission and generation planning process.

Many of the studies found that the systems already possess the needed flexibility, particularly at lower VG penetration levels; therefore, there may be no need to develop additional sources of flexibility.

The integration studies should be reviewed to identify best practices and to develop guidelines that can be adopted immediately for the use of and enhancements to existing planning tools for evaluating the flexibility needs that arise from the integration of VG. It should be recognized in this review process that many important issues are simply not covered and require additional study and effort to develop meaningful guidelines.

In addition to identifying the impact of VG on the characteristics of system flexibility and their implication for system planning, this report also identifies the many sources of increased flexibility available to system planners and operators. New sources such as demand-side management may be particularly attractive and need further study. Many of the most important sources may not be physical, but institutional; i.e., they unlock the availability of existing physical flexibility (e.g., forecasting, market design, etc.). This indicates that a portfolio of alternatives exists and is available to a power system to meet its flexibility requirements. These options would need to be evaluated within the context of any new enhanced system planning framework.

In summary, high penetrations of VG will result in the need for increased flexibility, which planning studies will need to account for. This report provides examples of how power systems that already have high levels of VG are adjusting operating practices and market structures in response to the increased variability. The task force began the challenging effort of developing a metric for flexibility but left further development to NERC and industry. Finally, the report did not identify specific changes to planning practices to account for the impact of VG but believes that a set of best practices to account for flexibility in planning studies now can be developed. A starting point is a number of excellent integration of VG studies that have been conducted in the recent past.

Summary of Recommendations

- Probabilistic planning methods being developed in the ongoing work of NERC's IVGTF Task 1-6 will be a vital improvement to assess required flexibility.
- System planners should document a set of best planning practices to design systems with sufficient flexibility to accommodate targeted levels of VG.
- The NERC Reliability Metrics Working Group (RMWG), after provision of metric templates, develops agreed-upon metrics:
  - Develop and collect metrics that measure flexibility needs for VG. For example, calculating a set of ramp and intensity metrics can provide insights on flexibility trends.
  - Compare projected and actual annual energy levels from VG.
  - Measure VG performance factors such as capacity factors and peak coincidence factors.

Task 1-5: Potential Reliability Impacts of Emerging Flexible Resources

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Potential Reliability Impacts of Emerging Flexible Resources.	Identify the need to assess reliability implications of integrating: • Plug-in hybrid electric vehicles • Storage devices • DR programs	Daniel Brooks November, 2010

The additional system variability and the reduced on-line conventional synchronous generation that may occur as more variable energy is delivered presents new challenges for power system operators to manage in the time frames of milliseconds to many days. To maintain the reliability of the BPS as more VG is integrated and other system enhancements potentially impact the ramp requirements of the system, sufficient and appropriate operational flexibility will be needed to respond to the resulting additional variability and uncertainty.

The Task 1-5 report summarizes the potential contributions that may be obtained in the future from emerging sources of flexibility such as DR, electric and thermal energy storage, and PEVs. As part of this assessment, the capability of each of the identified emerging resources to provide system flexibility/reliability functions and services was qualitatively evaluated for 10 specific characteristics: inertial response, primary frequency response, regulation load following, dispatchable energy, contingency spinning reserves, contingency non-spinning reserves, replacement reserves, VG tail event reserves, and voltage support. There are numerous challenges to quantifying the potential impact of these emerging flexible resources on bulk system reliability, including the lack of flexibility metrics, the uncertainty in quantifying future system flexibility needs, and the uncertainty due to the availability of the emerging flexible resources and other conventional resources that can supply flexibility. Consequently, this report provides a qualitative analysis of the potential of DR, distributed energy storage, and PEV technologies to provide the 10 specified reliability functions 10 years in the future.

An important conclusion from this assessment is that the emerging flexible resources evaluated—DR, distributed energy storage, and PEVs—offer the potential to support many of the flexibility-related reliability functions that may be challenged as VG levels increase. While many of these technologies have not yet been applied to providing specific reliability functions, in many cases there do not appear to be any technical limitations in doing so. The potential market penetration of these emerging resources in providing the reliability functions is dependent on commercial and policy considerations that may or may not support development of these capabilities. Although a particular emerging flexible resource may be technically capable of providing specific reliability functions, the extent to which it is developed will be influenced by whether it is economically viable relative to other available potential sources.

Assuming that future commercial and market policy circumstances perpetuate present trends, these emerging resources are most likely to have the most significant impact on the reliability functions that allow for the longest response times and limited duration of response, such as spinning and non-spinning reserves. This is primarily due to the high potential of loads to participate in these reliability services, the growing record of accomplishment of DR already providing these services, and the large potential resource base that already exists. The potential aggregate impact on the faster response, longer duration, or higher frequency of deployment reliability functions

such as regulation or dispatchable energy is more moderate. These characteristics are not as well suited for a wide range of loads to supply. While many energy storage technologies and PEVs are technically capable and able to provide these services, they are either not currently commercially available or there is uncertainty as to whether sufficient development of the resources will have more significant impact over the next 10 years.

Key Findings and Recommendations

The electric power industry should continue research and development activities to assess the flexibility needs for the regional and interregional systems of North America and evaluate the benefits of flexible resources and technologies on their respective systems.

If all resources are provided equal opportunity and information as to power system reliability needs, then system reliability requirements, markets, and commercial viability should determine what resources provide specific reliability functions to the grid. If the emerging flexible resources addressed in this report are to play a significant role in providing the additional flexibility needed to accommodate high levels of VG, the barriers and limitations identified in this report must be addressed. Limitations related to the resources themselves (e.g., technological limitations or commercial viability) will be addressed to the extent possible by technology developers if those entities determine there is broader economic incentive to do so. Other external limitations, however, need to be addressed in order for technology developers to make decisions on technology investments. To that end, it is recommended that the following be addressed:

Technical Developments

Development of an operational infrastructure that provides visibility and control (direct or indirect) of distributed resources such as DR and PEVs

- In order for the emerging distributed resources to be significant contributors to the bulk system reliability functions, appropriate communication systems and methods of aggregating the resources into larger resource blocks are likely needed. System operators will need to understand the operational state and energy capacity available to the system in real time via full integration into energy management systems (EMSs) and market operation systems. This development includes technical, administrative, and commercial aspects.
- Technical developments are needed to ensure proper communication capabilities and integration into EMS and market operation software platforms. Aggregation of the resources into larger blocks will require developing the administrative processes to aggregate and bid the blocks of resources into the appropriate markets.

Market Developments

Adjust market rules that unnecessarily limit the types of resources for providing specific reliability functions. Some markets specifically designate some classes of resources as unable to participate in supplying some services.

- To the extent that there are no technical limitations that would prevent a resource class from reliably supplying a given service, market rules should be adjusted to allow a variety of resource types to participate within stated performance specifications while ensuring that there are no follow-on adverse reliability consequences. Resource developers can then determine whether they can package any resource type to meet the performance criteria in an economically viable manner. Thus, market rules should be reviewed in all Regions to remove any unnecessary restrictions.
- Develop retail tariffs for PEV owners that would encourage charging during off-peak hours.

Standards

Adjust regional or federal Reliability Standards that limit resources that can be used for providing specific reliability functions.

- Similar to market rules, Reliability Standards may also limit certain resource groups from providing some reliability functions. For example, the NERC Glossary definition of spinning reserve references "unloaded generation," which has been interpreted as prohibiting load from participating. As with market rules, federal and regional Reliability Standards should be adjusted, if necessary, to allow all resource groups to participate in providing reliability services within specified performance criteria.

Education

It is important to raise owner and operator awareness of the potential benefits of offering incentives related to flexibility services. An example would be adjusting market prices to encourage a desired response from customers while at the same time discouraging an undesired response (e.g., developing a tariff for PEV owners that would encourage charging during off-peak hours and discourage charging during peak hours).

Task 1-6: Probabilistic Methods

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Probabilistic Methods	Summarize the potential influence on power system operating and planning decision problems of VG increased uncertainty.	Michael Milligan July, 2014
	Describe the role that probabilistic methods can play in improving the basis on which the various decisions are made.	

The IVGTF report highlighted the need for risk assessment and probabilistic methods to assist in the integration of VG. It did so primarily in the context of planning, but numerous references throughout the report also suggested that operations could benefit from improved methods that can broadly be referred to as probabilistic methods. Task 1-6 focused on probabilistic methods and is reflective of the increased attention that these methods are getting. Variability and uncertainty are not new to the power system, and part of this increased attention on probabilistic methods reflects advancements in computing speed and algorithms; methods that were previously intractable due to data size and computer processing time are increasingly within our reach. But growing levels of wind and solar energy are serving as catalysts for these efforts. For example, the NERC *Summer Reliability Assessment* points out that more probabilistically based methods will be needed as the penetration of wind energy and solar energy increases on the BPS.

To various degrees, other IVGTF tasks are related to probabilistic methods. Task 1-2, "Methods to Model and Calculate Capacity Contributions of Variable Generation for Resource Adequacy Planning," and Task 1-4, "Flexibility Requirements and Metrics for Variable Generation: Implications for System Planning Studies," are particularly relevant and in many ways are subsets of the probabilistic methods reported in Task 1-6.

The objective of Task 1-6 is to summarize the potential influence on power system operating and planning decision problems of increased uncertainty caused by high VG penetration levels, and to describe the role that probabilistic methods can play in improving the basis on which the various decisions are made.

NERC is adopting more probabilistic methods in general. For example, NERC is running a Pilot Probabilistic Assessment to produce enhanced resource adequacy metrics for the Long-Term Reliability Assessment. NERC has traditionally gauged resource adequacy using a deterministic Planning Reserve Margin metric. The pilot is investigating two probabilistic metrics: Loss of Load Hours (LOLH) and Expected Unserved Energy (EUE). Unserved energy can be monetized, although this can be difficult to do.

Key Findings and Recommendations

- **Reserves**: The level of specific reserves needed for VG integration is broadly understood; however, specific methods have not been rigorously tested and compared. The application of stochastic methods appears promising but needs validation and acceptance if they are to be successfully used.
- **Dispatch**: There is emerging work on probabilistic methods to dispatch conventional generation to minimize cost and maintain reliability in the presence of high levels of VG; however, there is a gap between academic work and practice as a result of limited experience with high levels of VG.

- **Commitment:** There has been considerable interest in stochastic unit commitment. Methods and approaches vary, and most of this work resides in the academic/research domain. Collaboration to evolve and move these methods into actual practice, when appropriate, is needed.
- **Maintenance:** Maintenance scheduling may be more difficult in market regions where there is limited central authority to coordinate scheduled maintenance, and high levels of VG will likely have a significant influence. Industry can develop and test methods to quantify the risk of both capacity shortfalls and flexibility shortfalls.
- **Generation planning**: New methods have been developed to begin quantifying flexibility needs and risks of insufficient flexibility within generation expansion planning algorithms, so that results balance investment in VG with investments in technologies that provide the flexibility that VG requires. There is room for improvement in these methods, as well as a need to evolve and move these approaches from the research community to industry practice.
- **Transmission planning**: There is evidence that stochastic approaches to transmission planning may yield more robust solutions; combining such methods with co-optimization of generation and planning decisions is particularly appealing but computationally challenging. However, these methods are new and emerging, and additional research and deployment of such methods may be useful.

Additional General Recommendations

- Work to develop and demonstrate efficient probabilistic techniques and solutions that are capable of addressing industry problems.
- Improve the understanding of probabilistic methods within the industry. The research community needs to work more closely with the industry to clearly demonstrate the benefits of probabilistic methods. The industry needs to clearly communicate shortcomings in deterministic methods and areas where probabilistic methods can be most fruitful. Cooperative efforts of the research and industry communities are needed to overcome the challenges in terms of both understanding and demonstration.
- More and better data is needed to allow the research and demonstrations to be meaningful and realistic—from real power systems, from VG resources, and for future VG deployment scenarios. Collecting and maintaining large data sets can be expensive, however, and stochastic methods generally require data that may not be readily available. Industry should discuss the trade-offs and costs versus benefits of collecting data that could help inform stochastic methods and the more rigorous assessments of various risks associated with power system planning and operations with high levels of VG.
- Because of the potential for a significant increase in the development and application of stochastic methods to help analyze the impacts of VG, NERC should perform a biannual assessment of development in this area. The IVGTF would be an appropriate home for this work.

Task 1-7: Performance of Distributed Energy Resources During and After System Disturbance – Voltage and Frequency Ride-Through Requirements

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Performance of Distributed Energy Resources During and After System Disturbance Voltage and Frequency Ride-Through Requirements	Discusses FRT and VRT potential requirements for VERs connected to distribution facilities and the potential BPS reliability impacts if VERs do not remain interconnected, stable, and operational during and after normally expected momentary system disturbances.	Mahendra Patel December, 2013

A large amount of distribution-connected generation may have a significant effect on the reliability of the BPS. Existing interconnection requirements for Distributed Energy Resources (DERs) do not specifically take into account potential effects on bulk system reliability. Of particular concern to BPS reliability is the lack of disturbance tolerance, which entails voltage ride-through (VRT) and frequency ride-through (FRT) capability. Under high-penetration scenarios, it is possible for a large amount of DERs to trip on voltage or frequency due to a transmission contingency, which could potentially affect BPS stability. The need for high-frequency tolerance is being discussed as part of a current FERC stakeholder consultation on interconnection procedures for small generators'[10] distribution-connected VERs. Like all other DERs, these resources are required to comply with IEEE Standard 1547, which requires DERs to disconnect from the grid within a short period of time after voltage or frequency falls outside a certain range. The results of the IEEE Standard P1547a ballot were announced in September 2013, and the outcome was that VRT and FRT capabilities are now permitted but not required.

In North America, VRT and FRT standards for both BPS-connected and distribution-connected generators are in a state of evolution. NERC Reliability Standard PRC-024-1 was recently approved as a relay-setting requirement. The standard requires that generator voltage and frequency relays not be set to trip within the specified frequency and voltage performance envelopes unless it is necessary to do so to protect equipment or meet one of several other exceptions. With respect to disturbance tolerance, DER interconnection standards are inconsistent with the direction in which bulk system standards are evolving.

Task 1-7 evaluated the possible exposure of negative reliability impact on the BPS due to the lack of VRT and FRT requirements for DERs and provides general guidelines for the revisions to IEEE Standard 1547 to minimize this negative impact. It discusses FRT and VRT potential requirements for VERs connected to distribution facilities and the potential BPS reliability impacts if VERs do not remain interconnected, stable, and operational during and after normally expected momentary system disturbances. The task force also reviewed potentially inconsistent and conflicting requirements in existing standards for BPS-connected and distribution-system-connected VERs. In addition, Task 1-7 provided guidelines for suggested changes in the VRT and FRT requirements for distributed generation that may be necessary to maintain power system reliability and provided recommendations for changes needed in requirements to preserve the expected levels of power system reliability. Task 1-7 did not address reactive requirements of VERs for voltage control or voltage regulation, though task force members strongly feel they are essential and can have significant contribution in normal operation as well as reliability of the system. Task 1-7 also did not address reactive injections during system faults.

[10] See FERC Docket No. RM13-2-000.

Key Findings and Recommendations

In North America, IEEE Standard 1547 is the de facto standard for DER interconnection.[11] The lack of voltage and frequency disturbance ride-through requirements in the standard has the potential to adversely affect the reliability of the BPS under conditions of relatively high DER penetration levels expected in the future. While NERC's authority is solely to ensure BPS reliability, the task force concludes that large amounts of distribution-connected resources, in aggregate, can pose risks to the reliability of the BPS.

To mitigate these potential impacts, IVGTF Task 1-7 recommends that the voltage and frequency disturbance trip levels in IEEE Standard 1547 be revised and explicit disturbance tolerance requirements be adopted. This section summarizes the IVGTF 1-7 task force's guidance for future efforts to update DER interconnection requirements.

When the IVGTF Task 1-7 report was created, two general recommendations for NERC actions had been provided, followed by several suggested general guidelines for consideration by the IEEE 1547 participants, recognizing that specific requirements would have to be established through a stakeholder process. The recommendations offered were motivated by the relatively rapid deployment of distribution-connected VERs in some areas, particularly PV; however, they are intended to apply to other DERs as well.

One of the challenges is that, while high penetration of DERs can have an impact on bulk system reliability, NERC Reliability Standards that require relays on BES generators to be set to allow voltage and frequency ride-through do not directly apply. The task force believes that NERC and other BPS stakeholders can play a constructive role in ensuring that the reliability implications due to lack of disturbance tolerance for distributed VERs and other DERs are addressed. The general recommendations that have been offered are:

- In the short term, NERC should engage in current efforts to revise DER interconnection standards by providing information; supporting the efforts of IEEE with transmission reliability subject matter experts; raising industry, regulator, and policy maker awareness; and encouraging the consideration of the explicit VRT and FRT for DERs. The initial focus should be on potential ways to adopt minimum-tolerance thresholds for VRT and FRT in the IEEE Standard 1547 while balancing against other important distribution issues, such as safety and protection/coordination.
- In the longer term, NERC should establish a coordination mechanism with IEEE Standard 1547 to ensure that BPS reliability needs are factored into the revision efforts of future DER interconnection standards. To date, BPS stakeholders have participated only sporadically in the IEEE Standard 1547 process. As a result, VRT and FRT concepts receive limited consideration and may have been outweighed by distribution system protection concerns. This liaison process would be timely for the full revision to begin in 2013 or early 2014.

The task force also offers general guidelines on VRT and FRT specifications for distributed VERs and other DERs for consideration in the P1547a process or future IEEE Standard 1547 revision.

The 2014 draft phase of the IEEE Standard is now underway with strong support in enhancing the ride-through requirements. These enhancements will, in the future, allow for DERs to regulate voltages and to support grid frequency. There is reasonable potential that this new version of the IEEE Standard 1547 may carry out NERC's IVGTF Task 1-7 recommendations on voltage and frequency ride-through requirements. However, there is also substantial risk that various interests may introduce clauses that essentially nullify the ride-through requirements, such as to make these requirements only applicable where they do not require any changes or enhancements of equipment capability. Continued monitoring of the IEEE Standard 1547 development is essential to ensure that effective ride-through requirements are enacted.

[11] Other international organizations have also adopted the IEEE Standard.

Task 1-8: Potential Bulk System Reliability Impacts of Distributed Resources

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Potential Bulk System Reliability Impacts of Distributed Resources	Identify the potential impacts of DER to reliability.	Daniel Brooks August, 2011
	Identify potential mitigating strategies.	
	Review existing NERC Registry Criteria specific to DER applications.	
	Propose potential future approaches to ensure continued reliability in systems with large amounts of DER.	

Task 1-8 differs from the other IVGTF tasks in the following respects:

1. Task 1-8 focuses on the bulk system impact of distributed resources; and
2. Task 1-8 considers the bulk system impact of all distributed resources, not just VG resources.

Task 1-8 addresses the potential BPS reliability concerns arising from the integration of large amounts of distributed resources, such as distributed solar PV, PEVs, distributed electric storage, and DR programs.

The following potential bulk system reliability impacts of high levels of DER have been identified:

- Non-dispatchable ramping/variability of certain DERs.
- Response to faults: lack of low-voltage ride-through, lack of frequency ride-through, and coordination with the IEEE 1547 interconnection standards for distributed generation, which is presently being revised.
- Potential system protection considerations.
- Under-Frequency Load Shedding (UFLS) and Under-Voltage Load Shedding (UVLS) disconnecting generation and further reducing frequency and voltage support.
- Visibility/controllability of DERs.
- Coordination of system restoration.
- Scheduling/forecasting impacts on base load/cycling generation mix.
- Displacement of bulk system resources that provide reactive power and voltage control and active power and frequency support to the system.
- Impacts on forecast of apparent load seen by the transmission system

These issues may impact the bulk system at different levels of penetration, depending on the characteristics of the particular area to which the DERs are connected. Some factors will need to be managed by technical requirements (grid codes) for the DER itself, while others need the bulk system operator to adapt new planning or operational methods. Significant amounts of DERs can affect the power flow on the transmission and sub-transmission systems, which can result in thermal overloads or significant changes in profile. The uncertainties

associated with the variable output (in aggregate) can create additional uncertainties in net demand to be served by transmission and balancing resources, with an added complication to the system operator of limited monitoring and control of the output from distributed resources. Certain regions, such as Hawaii or Germany, are already seeing significant challenges of the type outlined here. Studies and real world experience have shown the potential impact of significant penetrations of DERs. In particular, much attention has been focused on both the impact of variability and uncertainty, which can be invisible to the bulk system operator, and low-voltage or low-frequency response of DERs. High DER penetrations have been shown to affect the transient and small-signal stability of the system. This can be either positive or negative depending on the type of DER (e.g., inverter-connected DERs can adversely or beneficially affect stability depending on the control schemes employed).

Key Findings and Recommendations:

While specific recommendations for guidelines or standards are not provided, the following general recommendations are made:

Metric and Additional Research

1. NERC, state regulators, and/or industry should continue development of an analytical framework and basis for understanding the potential adverse reliability impacts and how the magnitude of these reliability impacts changes with penetration of DERs and system configuration/composition.
2. As many DER issues may be beyond the scope of NERC's authority, and since it may be feasible to address these issues through non-NERC avenues (such as market rules, vertically integrated operations, or state programs), it is recommended that NERC work with the affected entities in the different regions, including state agencies having jurisdiction over DERs, RTOs, and vertically integrated utilities, to develop appropriate guidelines, practices, and requirements to address issues resulting from DERs that impact the reliability of the BES.

Technical Developments

Based in part on the analytical results from the first recommendation in the metric and additional research above, and the broad experience of generation, transmission, and distribution owners and operators, specific recommendations for changes to operating and planning practices, state programs, and pertinent NERC Reliability Standards should be developed.

Task 2-1: VG Power Forecasting for Operations

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Variable Generation Power Forecasting for Operations	Discuss the forecasting requirements for the 48 hours of operation ahead and how forecasting information can be delivered to the system operator in a useful and actionable way.	Mark Ahlstrom May, 2010

The output of wind and solar power plants is subject to greater variability and uncertainty than conventional generation. This variability and uncertainty is due not to the generation technology, but to the implicit nature of the fuel sources (wind and sun) that are influenced by weather. Forecasting is one of the tools that can be used to address concerns and costs around this variability and uncertainty. The Task 2-1 report discusses operational and market system impacts, provides background on what can be realistically expected from VG power-output forecasting, and proposes recommendations to deploy forecasting systems into operational use.

The Task 2-1 report focuses on the operating time frame—from real time to the coming 48 hours. Forecasting of VG resources is important in all time frames, and there are many uses for longer-range forecasts from days and weeks (e.g., transmission outage planning and minimum generation issues) to years (e.g., integrated resource planning, where resource flexibility and ramping capabilities should be increasingly valued, and the generation mix—if not appropriately planned—can raise bigger challenges during the operating time frame). Such longer-term schedules are adjusted as they get closer to real time, and the critical operating impacts to BPS reliability tend to be closer to real time. Therefore, again in the interests of focus and expediency, this report primarily discusses the forecasting requirements for the coming 48 hours and particularly considers how forecasting information can be delivered to the system operator in a useful and actionable way.

Conclusions

- Aggregate forecast accuracy improves with the size of the region forecast, and aggregation across broad geographical regions can significantly reduce the uncertainty of output forecasts.
- Large system or market size and system flexibility improves the operator's ability to deal with variability.
- Methods for clear and efficient prioritization of renewable resources during curtailment conditions are important for both reliability and economics. For example, regional markets should evaluate adding negative curtailment pricing to their dispatch algorithms to encourage logical and efficient responses from all resources.
- VG power forecasts in multiple time frames are critical for maintaining both system reliability and economic operation.
- At any given time, the importance of the forecast to system reliability will depend on the operating state of the BPS.
- The accurate forecasting of ramp events potentially represents a significant challenge for power system reliability with respect to the integration of VG, although because the variability remains even when uncertainty is reduced, work toward improved forecasting must also be balanced with improvements in system operations and flexibility.

- The relative value of ramp forecasts will depend in part on the system posture. Uncertainty information surrounding the forecast can be provided in ways that best suit the needs of the system operator.
- Electrical (power, availability, curtailment) and meteorological data from wind and solar plants, delivered to the forecaster and system operator on a timely and reliable basis, are critical for forecast accuracy.

Key Findings and Recommendations

For the Industry

- Wind and solar plants require real-time meteorological and electrical data through SCADA systems using standard communication protocols for use in forecasting and system operation, including power, availability, curtailment, and meteorological data.
- Wind plant output forecasts, often several of them, should be adopted as standard system and market operation tools for economic operation and system reliability purposes. Multiple types of forecasts and forecast optimizations are practical and important.
  - Clarity around how a particular forecast will be used must be clearly defined for both the provider and user of a forecast product.
  - Given the value of incrementally better forecasts, system operators should consider a multiple-forecasting-provider model rather than using a single external or internal forecasting service.
  - A ramp forecast is possible and useful but may need to be optimized for a different use than the conventional power forecast. The “chance of ramp” indication is valuable even if it is not perfect. In fact, the complexity of weather events guarantees that ramp forecasts will not be perfect.
  - It may be beneficial to tune the wind power forecast to take into account the state of the power system. Morning load pickups and evening load drop-offs may require better knowledge of the likelihood of wind ramps and should be investigated by the system operator.
- How forecasts are used is what really matters.
  - Initial use of aggregate, regional, and individual wind plant forecasts by reliability coordinators in the control room is a logical first step.
  - Use of the forecast in unit commitment planning is very important. Appropriately clearing the day-ahead market with a combined load and wind power forecast (rather than ignoring the wind) will improve both the economics and reliability of system operation.
  - Probabilistic methods are increasingly important, and the uncertainty distributions around all forecasts (including but not limited to the VG power forecasts) should be addressed more explicitly. As a minimum, the use of a chance-of-ramp forecast probability should be used to identify whether or not additional reserves are needed.
- There are overwhelming benefits from adjusting operating rules and practices, and these adjustments may have more benefit to both reliability and economic operations than the forecasting alone.
  - Sub-hourly markets with sufficient liquidity, or the ability to otherwise dispatch generation closer to real time with sufficient flexibility, can be very effective in addressing the variability and uncertainty of VG.
  - Incorporating the VG power forecast into unit commitment is important for economical and reliable operation.
  - Negative price offers for resources should be included in markets that do not yet offer this capability to help maintain reliable and economical operation.

  - The benefits of larger balancing areas with fewer transmission constraints can be substantial. Resolving transmission constraints is critical because larger balancing areas lose many of the benefits associated with size if constraints are in play. Areas with sufficient transmission capacity are exploring how to achieve the benefits of larger areas through direct balancing area consolidation or through efforts at "virtual consolidation" where separate balancing areas work together on particular issues. Smaller areas, such as island systems, will have special challenges that require additional control. Larger operating areas with minimal transmission constraints and diverse VG assets should be capable of dealing with the expected levels of VG.

- Ongoing innovation is needed with both government and private industry involvement. Innovation is needed to continue to improve forecasting products. This requires multiple cooperating players:
  - Government R&D and forecasting centers for improved data systems, model development, and general operational weather deliverables;
  - A vibrant, competitive forecasting service community to assist in the R&D, applications, and services for business-augmented use of operating data with forecasting products;
  - Developers of system operating tools and methods, both in private companies and in the system operator organizations, to deal with the true variability and forecast probability distributions that are implicit to our real-world systems, system operators, and stakeholders.

For the Standards

The following recommendations were included in the original report. Many of these items have subsequently been addressed or reviewed by FERC Order 764 and ongoing standard development processes since the report was issued in 2010. Updated comments from the Task Lead are noted below in brackets but were not part of the original report or the report's approval process.

Table 4. IVGTF Recommended Standards Improvements

Standard	Definition	Recommendations
FAC-001	Facility Connection Requirements	The Transmission Owner's connection requirements for generation facilities (Section R2) should reflect the need for appropriate data from VG plants including power, availability, curtailment, etc. The standard may require a basic level of meteorological data from wind, solar, and other VG plants whose power output is influenced by local weather events. [For wind, this has been largely addressed with FERC Order 764 and grid codes.]
TOP-002	Normal Operations Planning	This standard may need to be updated to include a section about forecasting, identifying the data submitted by variable generators as the method of providing generation information to the Transmission Operators, and also recognizing forecasting as the best way to estimate generation, albeit subject to some unavoidable uncertainty due to the variability and complexity of weather conditions. [For

		wind, this has been largely addressed with FERC Order 764 and grid codes.]
TOP-006	Monitoring System Conditions	Requirement 1.1 could be interpreted as requiring availability information. Since availability information is useful for forecasting the output of variability of generation plants (like wind plants) with multiple turbines, this requirement should be reviewed to consider if the current language is sufficient. [FERC Order 764 includes the right for the system operator to obtain availability information (and other data) from wind plants if needed for forecasting.]
BAL-002	Disturbance Control Performance	The standard may need to be revised to include sudden changes in wind output as "credible contingencies" under the standard. This would ensure that these events are analyzed during reserve calculations. The applicable section of the standard is Requirement 3.1.
COM-002	Communication and Coordination	The standard may need to be revised to clarify the meaning of "voice and data links." To avoid problematic interpretations, the standard should specify that voice and data links are those identified in Interconnection Agreements or other governing agreements between the Transmission Operators and the variable generator.
IRO-005	Reliability Coordination – Current-Day Operations	This standard may need to be updated to include active monitoring of forecasting conditions such as weather fronts, icing, or high-wind conditions by the Reliability Coordinator. The active monitoring would ensure that the Reliability Coordinator is aware of conditions that may arise in the immediate future. This would create consistency with the purpose of the standard, which is: "The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas."

In addition to the above recommendations, NERC Reliability Standards that address the reasonable and effective use of regional forecasts and local wind/solar facility forecasts should be encouraged and used to schedule VG.

Task 2-2: BA Communications

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Reliability Considerations for BA Communications with Increased Variable Generation	Address communications requirements between the variable renewable generation plant and the BA.	Bill Grant March, 2012

Task 2-2 addresses communications requirements between variable renewable generation plants and the associated BA. Increased variability will require a robust communication network between BAs and plant operators to ensure the grid continues to operate reliably. Improved forecasting accuracy and expanded backup generation facilities (i.e., natural gas plants) with expedient ramp rates can help to alleviate these disadvantages. However, in order for wind generation to provide power plant control capabilities, it must be visible to the system operator and able to respond to dispatch instructions during normal and emergency conditions. Accordingly, enhanced communication protocols will be needed to ensure wind resources can become a more significant part of the North American generation mix without compromising grid reliability.

Real-time communication capabilities for system operators will continue to play an instrumental role, especially during system restoration efforts that require increased coordination between a given Balancing Area and the Transmission System Operator (TSO). The TSO's inability to access up-to-date information on the output of VG resources has caused consequences such as those seen during an event in November 2006, when the European grid experienced power disruption to over 15 million households. It was determined that grid operators lacked the capability to communicate data for variable wind resources, most of which were reconnecting to the distribution system automatically (as system conditions allowed). The lack of real-time visibility of these resources ultimately counteracted the TSO's efforts to effectively balance the system.

Communication protocols used by wind plants and other VG can range from basic telephone calls and emails to different SCADA (supervisory control and data acquisition) systems. Currently, no industry-wide protocols have been established. This report explores some of the BA communication protocols used in North America, with a focus on the effectiveness of these protocols in the absence of conformity.

The Task 2-2 report details the current data and communications requirements for wind plants in ERCOT, NYISO, PJM, BPA, Hawaii, AESO, BC Hydro, and Hydro Quebec.

Key Findings and Recommendations

Communication Recommendations for Wind Resources

The Task 2-2 report discussed and identified a range of data that would enhance the reliability of the BES. Specific data and associated communication requirements identified are already required in developed markets. These data and communication capabilities should be provided to the BA by all generation operating in the BA that has an impact on the reliability of the BES. These are listed as follows:

- Net and gross MW and MVAR output
- Meteorological data (wind speed, wind direction, temperature, and barometric pressure)
- High- and low-sustained limit

- Normal and emergency ramp-rate capability
- Turbine availability
- Breaker status
- Modeling data (static information)
  - Tower height
  - Relay settings (including UFR settings)
  - Type of turbines
- Voice circuit
  - Available communication to plant operator
  - Communication to address real-time operational issues
- Set point and curtailment communication (to Balancing Areas)

Currently, most of these requirements are not applicable for a significant number of smaller wind farms (less than 75 MW) unless they are covered in the interconnection agreement or the market rules (if applicable). Generators connected to the distribution system usually do not have these data and communication requirements in their interconnection agreements either but can have a significant impact on the transmission system. Several smaller wind farms, regardless of the interconnection to the transmission system or the distribution system, can in aggregate have a significant impact on a specific area of the BES. For these reasons we make the following recommendation:

All generators 10 MW or greater within a BA regardless of interconnection point shall provide:

- Breaker status to the BA/TOP (FAC-001)
- Current MW and MVAR output (FAC-001)
- Voice circuit for communication of real-time instruction (COM-002)
  - Remote control of resources is adequate but should be capable of handling real-time operational issues.
- Coordination of relay settings, specifically under-frequency coordination (FAC-001)

The following should also be required for all generators 10 MW or greater within a BA regardless of interconnection point, if a significant impact has been identified in an interconnection study:

- Resource schedules with outage information (FAC-001)
- Meteorological data for forecasting (FAC-001)
- Availability (FAC-001)
- High- and low-sustained limit (FAC-001)
  - Include high-wind cutout
  - Temperature limitations
  - Any other operational restrictions

Recommendations for NERC Standards

In order to implement these changes, the following standards will have to be reviewed and updated:

- **FAC-001**: Transmission Operators would list their specific requirements not only for generation connected to the transmission system but also any generation in the footprint that is within the area that will impact the operation of the BA and BES.
- **COM-002**: Consider applying the standard to all generation down to 10 MW or greater. This will not only improve data communication but also require the Generator Operator to be available to address real-time operational issues. This can be accomplished with manned resources or remote control and monitoring of the facilities.
- **PRC-001**: Make Requirement 3 applicable to facilities 10 MW or greater. This will ensure that the necessary relay coordination has taken place to reduce the reliability impact of unexpected relay operation, specifically operation of under- and over-frequency relays. The generation should be set lower than the UFLS relays in the region to ensure generation tripping does not compound under-frequency operation similar to the European event.
- **TOP-001**: Under Requirement 3, require all generation facilities 10 MW or greater to comply with reliability directives from the Balancing Authority or the Transmission Operator. Under Requirement 7, all generation facilities of 10 MW or greater should provide notice to the Balancing Authority and the Transmission Operator before removing generation facilities from service to reduce the reliability impact to the system.
- **TOP-002-2b**: Under Requirement 3, require all generation facilities 10 MW or greater to provide their current, next-day, and seasonal operations with the host Balancing Authority and Transmission Provider. This will improve the reliability studies of the BES.
- **TOP-003-1**: For generation facilities 10 MW or greater, require outage coordination of generation facilities including telemetering equipment and voltage regulation equipment so that interconnected operations are coordinated between Balancing Authorities, Transmission Operators, and Reliability Coordinators.

These changes should be reviewed and implemented in the next review cycle. Adding these requirements to the functional requirements with audit oversight will ensure the operators have the tools necessary not only for normal operations but also for abnormal operations and system restoration.

Task 2-3: Ancillary Services and Balancing Authority Area Solutions to Integrating Variable Generation

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Ancillary Services and Balancing Authority Area Solutions to Integrating Variable Generation	Address communications requirements between the variable renewable generation plant and the Balancing Authority.	Jay Caspary March, 2011
	Study provisions of ancillary services from other jurisdictions, ACE sharing, or shorter scheduling intervals within and between Balancing Authority Areas to manage and spread the effects from variability of generation resources over a larger footprint.	
	Review existing and proposed standards.	

Task 2-3 addresses ancillary service requirements with VG. Balancing generation and demand with increasing levels of VG using traditional ancillary service products and operating practices could become a challenge for BAs. The BA must keep in mind the potential reliability considerations and variables involved. Enhanced tools, used daily to determine reserve operating capacities, can reduce uncertainty in maintaining generation-load balance under increased VG resources. Studies have shown that balancing VG over large geographic areas such as RTO regions increases diversity of wind resources, thereby reducing the aggregate variability of the generation output.

The objective of this task was to assess the need for ancillary services from both inside and outside existing BA Areas and to assess the need for changes in operating practices due to additional VG. The NERC Operating Committee approved the formation of this task team to study the consequences of enlarging existing BA Areas or participating in wider and multiple BA Area management. This multiple Balancing Authority Area management would include provisions of ancillary services from other jurisdictions, ACE sharing, or shorter scheduling intervals within and between BA Areas to manage and spread the effects from variability of generation resources over a larger footprint. In addition, existing and proposed standards were reviewed to determine their sufficiency in response to these evolving conditions. This report developed a survey of current Regional Entities' operations and methods, including application of their Renewable Portfolio Standards (RPSs). This assessment evaluates NERC'S Reliability Standards and includes recommendations that were deemed appropriate by the team.

The Task 2-3 report includes a survey that reviews the ways each Regional Entity addresses frequency response, regulation, and spinning and non-spinning reserves. The regulation footprint for maintaining balance between generation and load is defined by metered boundaries within a BA Area. Within the aggregate of all BAs, all generation and load within the interconnection is monitored and regulated for generation-load balance. As defined in BAL-005, each BA Area is required to have Automatic Generation Control (AGC) and to calculate Area Control Error (ACE) and deploy regulating reserve to balance resources and demand.

Key Findings and Recommendations

The objective of this report is to explore different practices and instill awareness of how BA Areas depend on short- and long-term planning and forecasting, complemented by sound Reliability Standards and efficient operating practices. BA Areas may cope with high variability in many ways. BA Areas with low penetration of

variable resources may rely predominantly on ancillary services packaged in a variety of specific products. In contrast, many BA Areas or regions with high penetration of variable resources have already developed broader regional solutions to maintaining energy balance.

The general observation, however, is that increased variability of generator output requires increased flexibility of dispatch operations. Therefore, the task force embarked on answering the following questions: What are the BA rules each entity most follow? Further, how will the existing 100-plus BAs operate in a homogenous way to address ancillary service requirements from VG?

Recommendation 1: Each region or reserve-sharing group should permit contingency reserve deployment under imbalance energy circumstances that are made more likely with the increasing penetration of renewables.

Recommendation 2: The task team recommends that the generator interconnection requirements be modified to require this dispatchable control capability to interface with the grid operator for all new VG resource developments.

Recommendation 3: Regional market operators and other grid-operating entities should develop the ability to consider transmission service by prioritizing variable resources when allocating curtailment responsibility to variable output resources during reliability-limited operating conditions.

Table 5. Recommendation to Reliability Standards

Standard	Definition	Recommendations
BAL-001-0.1a	Real Power Balancing Control Performance	Increase BA collaboration to reduce cost overall and to make it valuable for integration of VG.
BAL-002-0	Disturbance Control Performance	The standard drafting team should consider if contingency reserves can be used to meet DCS requirements for wind-related events. Reserve calculation procedures should be updated to take into account variable energy resource events including ramping events that are much slower than the instantaneous contingency events caused by conventional generators and transmission failures. This could impact recommendations for Contingency Reserve Policies, DCS, DCS response time, and DCS recovery time.
		Alternatively, the current BAL-002 and DCS do not apply to variable energy resource events because they are too slow. There is no need to change BAL-002 due to variable energy resource integration. Balancing Authorities would need to deal with the risk of tail events with their own resources—or with different resources than the current DCS resources. Ultimately, it would be more efficient to mitigate the risk of rare tail

		events by using pooled reserves, especially in high-penetration scenarios.
		Action: **IVGTF2-3 should collaborate with the standards drafting team to establish another requirement to accommodate VERs and their tail events.**
IRO-005-3-1a	Reliability Coordination — Current-Day Operations	A NERC standard is required to communicate VG derates due to turbine outage conditions and plans. Currently issues may arise if part of a wind plant is out of service and operators are not aware of the number of turbines unavailable and duration of the forced or planned outage.
TOP-002-2&A	Normal Operations Planning	The standard should be enhanced to provide guidance on incorporation of variable energy resource events into the planning process.
TOP-006-1&2	Monitoring System Conditions	Expand R4 to require similar information and prediction of VG output: R4. Each Transmission Operator and Balancing Authority shall have information including weather forecasts, and past load and variable generation patterns are available to predict the system's near-term load and variable generation pattern.

Task 2-4: Operating Practices Procedures and Tools

Task Summaries

Special Assessment Report	Objective	Task Lead and Approved Date
Operating Practices Procedures and Tools	Discuss VG impact on power system operations.	Brendan Kirby March, 2011
	Discuss the need to modify operating practices, procedures, and tools.	
	Address the impacts on commitment and/or dispatch along with reserve management practices.	

Key Findings and Recommendations

NERC Standards

One of the goals of Task 2-4 is to evaluate needed changes to NERC's Reliability Standards. Several NERC Reliability Standards may need to be updated. The following standards require enhancement:

- **BAL-002** (Disturbance Control Performance) – This standard may need to be revised to include sudden changes in wind output as "credible contingencies." This would ensure that these events are analyzed during capacity reserve margin calculations. The applicable section of the standard is Requirement 3-1. Additionally, changes to this standard may need to be addressed with various reserve-sharing groups, many of which have differing rules regarding contingencies.
- **BAL-005 R11** (Automatic Generation Control) – This standard may need to be updated to include the various types of ramp rates that a BA may need to use in the Scheduled Interchange values to calculate ACE. Controlled and uncontrolled ramp rates may need to be included in the analysis since both types can be encountered by VG.
- **COM-002** (Communication and Coordination) – The standard may need to be revised to clarify the meaning of "voice and data links." To avoid problematic interpretations, the standard should specify that voice and data links are those identified in Interconnection Agreements or other governing agreements between the Transmission Operators and the variable generator.
- **EOP-002 R6 (Capacity and Energy Emergencies)** – This standard may need to be updated to reflect curtailment capabilities of various types of generation as one of the possible remedies available to BAs. This would ensure that a BA has examined various types of remedies that are available when experiencing problems meeting the Control Performance and Disturbance Control standards.
- **IRO-004** (Reliability Coordination – Operations Planning) – This standard may need to be updated to reflect forecasting information available to VG that is to be made available for next-day studies. Currently, the standard indicates that parties "shall provide information required for system studies, such as critical facility status, load, generation, operating reserve projections, and known Interchange Transactions." Forecasting of VG could be added to the list to provide an accurate day-ahead study.
- **IRO-005** (Reliability Coordination – Current-Day Operations) – This standard may need to be updated to include active monitoring of forecasting conditions such as weather fronts, icing, and high wind conditions by the Reliability Coordinator. The active monitoring would ensure that the Reliability Coordinator is aware of conditions that may arise in the immediate future. This would create consistency with the purpose of the standard, which is: "The Reliability Coordinator must be continuously aware of conditions

within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas."

- **TOP-002** (Normal Operations Planning) – This standard may need to be updated to include a section about forecasting that identifies the data submitted by variable generators as the method of providing generation information to the Transmission Operators, and also recognizes forecasting as the best way to estimate generation, albeit subject to some unavoidable uncertainty due to the variability and complexity of weather conditions. This would assist in system operations, especially in day-ahead or hour-ahead operations.
- **TOP-006** (Monitoring System Conditions) – Requirement 5 of this standard discusses the use of "monitoring equipment to bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action." This standard may need to be revised to include specific tools, such as (1) input from a forecaster, or (2) real-time data from wind and solar plants (e.g., meteorological towers, sonic detection and ranging (SODAR), and real-time turbine telemetry).

In addition, NERC Reliability Standards that address the reasonable and effective use of regional forecasts and local wind or solar facility forecasts should be encouraged and used to schedule VG to assist in accurate system operation.

Other Conclusions and Recommendations

Improved operating practices, procedures, and tools can help reliably integrate VG into the power system as well as improve the reliability of the power system in the absence of VG. Reliability resources such as flexible generation and responsive load are finite. Operating practices, procedures, and tools that reduce variability and uncertainty while maximizing the effective use of limited responsive resources improve reliability and facilitate VG integration.

Variability and uncertainty can be reduced through aggregation. Larger aggregations of wind and solar generation are proportionately less variable. Forecast accuracy is also improved for larger wind and solar aggregations. Net variability is reduced when VERs are aggregated with load, and it is net variability that must be balanced to maintain reliability. The pool of flexible resources (generators and responsive load) increases as the size of the BA is increased. Balancing should be conducted over the largest geographic area possible, either through consolidating smaller BAs or through coordinated operations.

Wind and solar forecasts become more accurate closer to real time. Unit commitment and economic dispatch should be performed as close to real time as possible. Five-minute economic scheduling of generation is common in North America. The IVGTF suggests that those Balancing Areas who face significant integration of variable resources consider studying the benefits of sub-hourly scheduling to manage the integration of VG. Depending on the current or projected BA system characteristics, assuming sufficient transmission is available, there may be benefits to intra-hour interchange scheduling, in the form of reduced ancillary services, and more flexibility and ability to manage the variability while still meeting the requirements of NERC's Reliability Standards.

Conclusions:

- Increasing system variability increases the importance for operators to have visibility of system conditions, access to tools to resolve conditions, and clear rules on when to implement those tools.
- Aggregate forecast accuracy improves with the size of the forecast region.

- Aggregation across broad geographical regions significantly reduces output variability and associated operating reserve requirements. In general, the aggregate uncertainty should also be mitigated by such aggregation, but the uncertainty and impacts from rare events may require more consideration.
- Large system or market size and flexibility improve the ability to deal with variability.
- Methods to ensure efficient prioritization of renewable resources during curtailment conditions are important for both reliability and economics. For example, regional markets should evaluate adding negative curtailment pricing to their dispatch algorithms to encourage logical and efficient responses from all resources.
- Electrical (power, availability, curtailment) and meteorological data from wind and solar plants, delivered to the forecaster and system operator on a timely and reliable basis, is critical for forecast accuracy and reliable operations.

Recommendations:

- Wind and solar plants should have the capability to send and receive real-time data (meteorological and electrical) through SCADA systems using standard communication protocols for use in forecasting and system operation.
- Wind plant output forecasts, often several of them, should be adopted as standard system and market operation tools for economic operation and system reliability purposes. Ramp forecasts as well as hourly energy forecasts should be considered.
- NERC Regions should consider what control capabilities should be required for new VERs to ensure reliability. Procedures should be developed that limit the use of VER control capabilities to situations where it is required to maintain reliability or when accepting the energy results in excessive costs.
- Interconnection requirements for all generation technologies (VER and conventional) need to be designed for anticipated rather than existing conditions, considering aggregate impacts and effects of displacing conventional generation. Interconnection requirements should address control capability, ride-through, inertial response, voltage regulation, etc. It is difficult to modify requirements on existing facilities after the fact.
- Tools including visualization are needed for system operators to process and present the wide range of information (aggregate forecasts, status of VERs, ramping capabilities, geographic coverage of ACE sharing, etc.) to the system operator.
- Changes to operating rules and practices are critical:
  - Sub-hourly markets with sufficient liquidity, or the ability to otherwise dispatch generation closer to real time with sufficient flexibility, can be effective in addressing the variability and uncertainty of VG.
  - Incorporating the VG power forecast into unit commitment and dispatch procedures is important for economical and reliable operation.
  - More frequent unit commitment can use updated forecasts of VERs and load.
  - Consider adjusting reserve requirements based on forecast VER output levels. This would allow the reserves to capture the fact that the volatility of wind output is different for different output levels.
  - Mechanisms to incent dispatch behavior consistent with system needs are required. For example, the interaction between variable resources supported by tax credits and renewable energy credits or monetized environmental benefits and a significant proportion of base load generation with significant minimum generation requirements suggests that the capability to capture negative price offers for resources may be needed to clear markets.

- The benefits of larger Balancing Areas with fewer transmission constraints can be substantial. Resolving transmission constraints is critical because larger Balancing Areas lose many of the benefits associated with size if constraints are in play. Different parts of the country are exploring how to achieve the benefits of larger areas through direct Balancing Area consolidation or through efforts at "virtual consolidation" where separate balancing areas work together on particular issues. Smaller areas, such as island systems, will have special challenges that require additional control. Larger operating areas, with minimal transmission constraints and diverse VG assets, should be capable of dealing with the expected levels of VG.
- Task 2-4 recommendations have suggested potential enhancements for consideration by the standards authorization drafting groups.

Conclusions and Recommendations

This report summarizes the findings from the total IVGTF multi-task effort. Findings and recommendations provide a reference manual of best practices for planners, operators, regulators, developers, and investors dealing with the challenges and opportunities offered by VG. Specific recommendations for standards development are included. This report also highlights areas that require further study and development; some are technological and others are institutional in nature.

The task reports note that the growth of wind and solar generation is not happening in isolation. Variability and uncertainty from VG must be considered in the context of the variability and uncertainty of load as well as the probability of conventional generation and transmission contingencies. Tools, standards, and operating practices must address the aggregate power system to ensure reliability at least cost.

While there are numerous recommendations for greater specificity in standards and interconnection requirements, as well as improvements in operator analysis tools and operating practices, there are also acknowledgements of developments that will likely ease VG integration challenges. The NERC *2013 Long-Term Reliability Assessment* notes that over the next 10 years there will likely be a shift toward a dramatically different resource mix with greater reliance on natural gas and renewable generation. NERC also expects about 71 GW of fossil-fired generation (primarily coal) to retire by 2022. While this shift to gas-fired generation raises fuel diversity concerns, it will also likely result in a conventional generation fleet with greater flexibility that is better able to accommodate the increased variability and uncertainty of VG.

DR is expected to grow as well, further enhancing the system's flexibility. NERC-wide, demand-side management (DSM) is projected to total roughly 80,000 MW by 2022 (or about 7 percent of the on-peak resource portfolio), offsetting approximately six years of peak demand growth.

Another positive trend is the growth in transmission to accommodate new and distant resources. As recently as five years ago, transmission was being constructed at a rate of about 1,000 circuit miles per year. In the last five years, over 2,300 circuit miles were constructed per year, more than doubling actual builds in the previous five years. With the current plans in place, that rate is expected to increase to 3,600 miles per year over the next five years. NERC-wide, almost a quarter of new transmission is specifically linked to the integration of renewable generation.

The IVGTF effort should be an ongoing process that incorporates the greater operating experience that continues to be gained and that reflects the advances in equipment and analysis tools. As it works through NERC's process for reviewing and developing standards, IVGTF recommendations for standards requirements should be considered promptly by standard drafting teams, entities, and by NERC's special assessments. In some cases, standards have already moved forward during the development of the IVGTF reports, sometimes in agreement with the IVGTF recommendations and sometimes not, and the IVGTF recommendations should be considered in light of these dynamic changes.

NERC staff will continue to monitor the progress of the IVGTF recommendations and recommends disbanding the IVGTF and delegating this continuing effort to NERC reliability and special assessment reports. With the commissioning of the Essential Reliability Services Task Force (ERSTF), which carries out actions for enhancing system reliability due to changes facing the BPS, NERC staff recommends transitioning related IVGTF work on recommendations to the ERSTF work plans and activities.[12]

[12] NERC commissioned the ERSTF to study, identify, and analyze the planning and operational changes that may impact BPS reliability. This task force is jointly commissioned between NERC's Planning and Operating Committees. More information on the ERSTF work plan and activities can be found at the ERSTF Webpage.

Appendix I

Transition Plan on IVGTF Recommendations	
Task 1-1 Standard Models for Variable Generation	
Transition Category	Planning –Technical Guidelines
Recommendation: The NERC standard FAC-001 should be expanded to clearly cover modeling requirements during the coordinated joint study phase of the Facility connection process. Simple generic models of variable generation may be adequate for the IES phase and more detailed models may be needed for the IFS phase. Validation of the simple and detailed model parameters may be needed during commissioning. **Response:** Mandating how system impact and facilities studies are completed is not appropriate and should not be part of a Reliability Standard. This level of prescriptiveness goes against the results-based approach for Standards. FAC-001 was just revised and the technical experts on the SDT and stakeholders did not agree that this level of prescriptiveness was appropriate. Therefore, no action is needed in NERC standards; this is a comment for utilities and ISOs to consider for interconnection agreements.	
Transition Category	Planning –Technical Guidelines
Recommendation: MOD-011 and MOD-012[13] Apply VG as a source of generation. **Response:** The proposed modifications generally align with the DG SDT's position on MOD-032. The DG SDT recommends leaving the existing standard language as is, but for NERC to publish guidance documents on how to best model dispersed generating resources. In particular, the SDT suggested that the guidance should "…require modeling requirements for each type of dispersed generation resource within a facility and aggregate model for each reasonable aggregation point," similar to the additional language being proposed by the IVGTF to be added to attachment 1. Note that while one or two individuals who have participated in some of the DG SDT meetings have argued that detailed models should be provided by DG resource owners of the entire site all the way down to the individual resources (versus providing an aggregate model/equivalent unit), this was generally dismissed by the DG SDT. It was the SDT consensus that an aggregate model/equivalent unit was sufficient and we currently agree with this position. NERC will publish guidance documents on how to best model dispersed generating resources. **Recommendation: MOD-013:** Include an explicit statement to cover VG. **Response:** Solar thermal dynamic models will be very similar to a typical fossil generating unit; while the fuel source is different, the steam turbine and generator components will be similar. For discussion, large-scale battery storage is a possible addition to this list. Our current assumption is that while battery storage technologies are diverse, their inverter-based interface will generally be similar to PV systems, so perhaps they can be covered in a way that is comparable to photovoltaic systems.	
Transition Category	No Action
MOD-024-1 Recommendation: Require wind units' total gross capability methods as the sum of the nameplate rating of all individual units. **Response:** Since losses due to the collection system are inherent to the design of a wind or solar site (vs. auxiliary equipment that could theoretically remain offline during the testing), no specific instructions should be needed to ensure that these are accounted for during testing. However, there is a section in attachment 1 (page 15 item 3.7) for the entity to provide the GSU losses if testing values were taken on the high side of the GSU. Assuming most entities will perform this testing at an aggregate level rather than at an individual unit basis, if collection system losses were	

[13] MOD-011 Standard is supported by MOD-025-2 Attachment 1 Item 2.1.2. http://www.nerc.com/_layouts/PrintStandard.aspx?standardnumber=MOD-025-2&title=Verification_and_Data_Reporting_of_Generator_Real_and_Reactive_Power_Capability_and_Synchronous_Condenser_Reactive_Power_Capability

deemed useful information to be provided to the Transmission Planner (and in fact, it might not be relevant data for the TP), this would be the location for it. Task leads suggest a 3.7.1 bullet point stating something along these lines: "For variable generating units such as wind or solar that utilize a collection system designed for aggregating the generation to a common point of connection, record the collection system losses (real or reactive)." The Drafting Team for Project 2014-01, in light of the revised BES definition approved by FERC in 2014, approached revisions to the standards with a general intent to maintain the status quo for applicability of the standards as they have been applied over time with respect to dispersed generation resources, where the status quo does not create a reliability gap.

Transition Category	Standards Review and/or Standard Authorization Request (SAR)

MOD-026-1 Recommendation: Standards are tailored explicitly to deal with synchronous-type generators, and items need to be clarified in these standards as they pertain to VG, particularly for:

- Unit/plant size for validation
- Validation of various technologies in a single plant
- Validation of different control layers
- Modeling and model validation
- Future functionality
- Modeling of protection
- Issues related to the fuel source for VG
- Model revalidation

Response: MOD-025-2 already does require confirmation of reactive capability of variable generation such as wind and PV solar. Section 2.1.2 of attachment 1 states the following:

- Verify variable generating units, such as wind, solar, and run-of-river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of Reactive Power capability of wind turbines and photovoltaic inverters with at least 90 percent of the wind turbines or photovoltaic inverters at a site on-line. If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, document the reasons the threshold was not met and test to the full capability at the time of the test. Reschedule the test of the facility within six months of being able to reach the 90 percent threshold. Maintain, as steady as practical, Real and Reactive Power output during verifications.
- Typical wind and solar sites have installed reactive capabilities in order to ensure they can meet the power factor requirements that are usually listed within their interconnection agreements. Verification that a site can meet its power factor requirements (often 95% lag and lead) would remove the variable nature of the generation from the reactive power verification testing. The 90% of wind turbines/solar inverters online requirement should be maintained for this testing.

Project 2007-09 addressed revisions to a number of standards in the MOD and PRC families. As a result of that project, MOD-025-2 was developed and is subject to future enforcement.

MOD-025-2 R1 states, "[e]ach Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: . . . [v]erify the Real Power capability of its generating units in accordance with Attachment 1." Section 2.1.2 of Attachment 1 requires the entity to: "[v]erify variable generating units, such as wind, solar, and run of river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of Reactive Power capability of wind turbines and photovoltaic inverters with at least 90 percent of the wind turbines or photovoltaic inverters at a site on-line. If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, document the reasons the threshold was not met and test to the full capability at the time of the test. Reschedule the test of the facility within six months of being able to reach the 90 percent threshold. Maintain, as steady as practical, Real and Reactive Power output during verifications."

The recommendation appears to be adequately addressed through the combined requirements of MOD-025-2, Attachment 1, Item 2.1.2; MOD-026-1; and MOD-027-1 (to include footnote 3b). Transmission Planners will have access to the information obtained as a result of MOD-025-2, which will then be used in compliance with MOD-026-1 and MOD-027, thereby ensuring variable generation is consistently and appropriately accounted for through the complementary design of the MOD standards.

MOD-025-2, which is subject to future enforcement, includes as R1 the requirement, "[e]ach Generator Owner shall provide its Transmission Planner with verification of the Real Power capability of its applicable Facilities as follows: . . . [v]erify the Real Power capability of its generating units in accordance with Attachment 1." Section 2.1.2 of Attachment 1 requires the entity to: "[v]erify variable generating units, such as wind, solar, and run of river hydro, at the maximum Real Power output the variable resource can provide at the time of the verification. Perform verification of Reactive Power capability of wind turbines and photovoltaic inverters with at least 90 percent of the wind turbines or photovoltaic inverters at a site on-line. If verification of wind turbines or photovoltaic inverter Facility cannot be accomplished meeting the 90 percent threshold, document the reasons the threshold was not met and test to the full capability at the time of the test. Reschedule the test of the facility within six months of being able to reach the 90 percent threshold. Maintain, as steady as practical, Real and Reactive Power output during verifications."

However, the current DGR SDT position (from currently posted version of the White Paper) is as follows:

4.7.5 MOD-025-2 — Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability. The purpose of MOD-025-2 is to ensure that accurate information on generator gross and net Real and Reactive Power capability is available for planning models used to assess BES reliability. This standard is appropriate for and includes specific provisions for dispersed generation resources to ensure changes in capabilities are reported. Therefore, the SDT is further evaluating whether to revise the applicability of the standard to align the language with the revised BES definition.

MOD-027 includes footnote 3b, which clarifies, "Turbine/governor and load control or active power/frequency control: . . . Active power/frequency control applies to inverter connected generators (often found at variable energy plants)." Further, the applicability of MOD-026-1 and MOD-027 has been designed to capture approximately 80% of available generation; therefore, facilities are subject to the requirements if those facilities are included in the guidelines.

OD-025-1 Recommendation: Clarification may be needed. Namely, VG reactive capability of the "power plant" is not entirely inherent in the individual generating units regarding how the total reactive capability of the power plant is defined.

Task 1-2 Methods to Model and Calculate Capacity Contributions of Variable Generation for Resource Adequacy Planning	
Transition Category	Planning –Technical Guidelines

Recommendations:

- Additional research to equate traditional reliability targets (such as a LOLE of 0.1day/year) to alternative metrics.
- LOLP, LOLE, or other related metrics should be used to calculate generation adequacy and capacity contributions of VG.
- More widely adopted energy-related reliability metrics and targets as the share of variable generation increases in the power system and recommend comparisons of results based on these alternative metrics.
- Planning reserve margin, calculated as a percentage of system peak, will become less meaningful with large penetrations of variable generation. Planning reserve margin levels should be periodically benchmarked with, or derived from, an LOLP or related approach to resource adequacy to ensure the account for any changes.
- Alternative approaches and assumptions regarding the treatment of interconnected systems should be transparent to the analysis.

- Development of one or more common approaches for handling the impact of interconnected systems in the reliability assessments.
- Simplified approaches should be benchmarked and calibrated to the rigorous ELCC calculations to ensure the validity of the approximation.
- The Ramp Response characteristic includes the rate of ramping required from flexible resources and the predictability of the ramp.

Transition Category	Data Collection

Recommendation: NERC should design and implement a way to collect high-quality variable generation data that would help inform calculations of capacity value.

Transition Category	NERC Reliability Assessments and External Coordination Activity

Recommendations:

- NERC should request that government agencies like the DOE, working with NOAA/NCAR, develop annual high-resolution, modeled wind and solar power data on 10-minute time scales and 2 km geographic grids.
- NERC should facilitate the dissemination of information about how LOLP-related reliability and adequacy calculations perform and what they measure.

Task 1-3 Interconnection Requirements for Variable Generation

Transition Category	Standards Review and/or SAR

Reactive Power and Voltage Control

Recommendation: NERC should consider revisions to FAC-001 expanding R.2.1.3 or create an appendix stating that interconnection standards for reactive power must cover specifications for minimum static and dynamic reactive power requirements at full power and at partial power, and how terminal voltage should affect the power factor or reactive range requirement. NERC should promote greater uniformity and clarity of reactive power requirements contained in connection standards that Transmission Operators have issued pursuant to FAC-001. NERC, FERC, and other applicable regional standards should be reconciled.

Response: VAR-001-4 R4 and R5 specifically call out "AVR" in the language. "AVR" is a term specific to conventional generation technology using synchronous machines with closed-loop voltage control executed by an exciter at each generator. "AVR" does not refer to the plant-level closed-loop voltage control provided by wind and solar plants. Wind and solar plants have the capability to regulate voltage and follow voltage schedules per the VAR-001 standards using a "plant-level volt/var controller." If "AVR" alone is used in the standard(s), it covers synchronous generation technology only and inherently neglects and could be interpreted to exempt wind and solar technologies from regulating voltage. There is also precedent in other existing NERC standards (such as MOD-026 and MOD-027) to specifically call out appropriate terminology for BES-connected wind and solar facilities to be sure these technologies are appropriately captured for the standard's applicability. The Task 1-3 team strongly believes that if AVR terminology is used in the standard at all, it should be revised to say "AVR or plant-level volt/var controller" to appropriately capture all generation technologies. The team recommends a white paper on the relationship between dynamic var capability and grid reliability to support a standard development activity.

Recommendation: NERC should consider revisions to VAR-001 standards to include the term "plant-level volt/var controller" (in addition to "AVR"), which is more appropriate for variable generation.

Response: VAR-001-4 R4 and R5 specifically call out "AVR" in the language. "AVR" is a term specific to conventional generation technology using synchronous machines with closed-loop voltage control executed by an exciter at each generator. "AVR" does not refer to the plant-level closed-loop voltage control provided by wind and solar plants. Wind and solar plants have the capability to regulate voltage and follow voltage schedules per the VAR-001 standards using a "plant-level volt/var controller." If "AVR" alone is used in the standard(s), it covers synchronous generation technology only and inherently neglects and could be interpreted to exempt wind and solar technologies from

regulating voltage. There is also precedent in other existing NERC standards (such as MOD-026 and MOD-027) to specifically call out appropriate terminology for BES-connected wind and solar facilities to be sure these technologies are appropriately captured for the standard's applicability. The Task 1-3 team strongly believes that if AVR terminology is used in the standard at all, it should be revised to say "AVR or plant-level volt/var controller" to appropriately capture all generation technologies.

Recommendation: NERC should consider initiating a Standards Authorization Request (SAR) to establish minimum reactive power capability standards for interconnection of all generators, and provide clear definitions of acceptable control performance.

Response: NERC may initiate a SAR in order to determine industry need.

Recommendation: Applicability: Generator interconnection requirement for reactive power should be clearly established for all generator technologies. NERC should consider giving transmission planners some discretion to establish variance based on the characteristics of their transmission systems and the sizes of the generators.

Recommendation: Specification of Reactive Range: The reactive range requirement should be defined over the full output range, and it should be applicable at the point of connection.

Recommendation: Impact of System Voltage on Reactive Power Capability: It should be recognized that system voltage level affects a generating plant's ability to deliver reactive power to the grid and the power system's requirement for reactive support.

Recommendation: Specification of Dynamic Reactive Capability: The standard should clearly define what is meant by "Dynamic" Reactive Capability by specifying the portion of the reactive power capability that is expected to be dynamic. A prospective standard should specify the minimum performance characteristic of the response in terms of response time, granularity (maximum step size), and repeatability (close-open-close cycling capability).

Recommendation: Definition of Control Performance – Expected volt/var control performance should be specified, including minimum control response time for voltage control, power factor control, and reactive power control. An interim period for the application of precisely defined control capabilities should be considered.

Recommendation: Effect of Generator Synchronization on System Voltage: Synchronization of generators to the grid should not cause excessive dynamic or steady-state voltage change at the point of connection. A 2 % limit may be considered as a baseline.

Recommendation: Special Considerations: NERC should investigate whether transmission operators can, under some conditions, allow variable generating plants to operate normally or temporarily at an active power level where dynamic reactive capability is limited or zero.

Recommendation: Technical Alternatives for Meeting Reactive Power Capability – The reactive power requirements should be applicable at the point of interconnection.

Recommendation: Commissioning tests – Commissioning tests, which are part of the interconnection process, often include a test to demonstrate plant compliance with reactive power capability requirements.

Transition Category	NERC Staff – External Coordination Activity

Performance During and After Disturbances Recommendations

1. The scope of PRC-024-1 should be broadened to cover smaller plant sizes. The current proposal of 75 MVA will miss many variable generator facilities that could impact the BES. It is suggested that the scope be broadened to cover all projects under a Large Generator Interconnection Agreement.
2. Or extend the scope to any project greater than 10 MW in order to provide coverage for plants not included under IEEE 1547.

Industry should decide the appropriate threshold (10 vs. 20 MW or MVA) as Regional Entity differences may be justified. Applicability should depend on total plant rating and should not be based on individual unit size. The BES definition describes facilities that are included in, and excluded from, the BES. If it is determined that a facility (or aggregation of units) impacts BES reliability, that facility will be accounted for through the BES inclusion process.

Standards for Manufactured Equipment Recommendation

Current solar PV inverters designed to comply with IEEE 1547 are required to provide anti-islanding capability and disconnection requirements that are not compatible with the fault ride-through requirements recommended here. Although individual inverters may have capacities on the order of 500 kW, utility-scale PV plants may have hundreds of these units and hence have a plant capacity of upwards of 100 MW. Furthermore, the inverters are listed at UL-1741, which is based on the requirements of IEEE 1547. This report recommends that new standards are proposed for utility-scale PV plants in order to drive the industry toward the adoption of new inverter specifications, testing, and certification.

Response: The team recommends that NERC keep track of the growth of variable generation that falls outside the NERC BES definition.

NERC should establish a coordination mechanism with IEEE Standard 1547 to ensure that BPS reliability needs are factored into the revision efforts of future DER interconnection standards. To date, BPS stakeholders have participated only sporadically in the IEEE Standard 1547 process. NERC should also encourage some BES reliability experts from utilities and ISOs to participate with the IEEE 1547 standard drafting process.

Transition Category	No Action

Recommendation: PRC-024 should clearly define performance requirements for unbalanced and balanced faults. The specification of voltage magnitude should define what voltage metric is applicable.

Transition Category	Standards Review and/or SAR

Disturbance Ride-Through Group

Recommendation: Voltage disturbance performance requirements, particularly high-voltage ride-through, should use the severity-cumulative duration form of specification to avoid unnecessary increase of VER plant costs to meet voltage disturbance durations that will never occur in practice.

Recommendation: Ride-through plots should be provided that specify both high- and low-voltage ride-through requirements. It is recommended that the zero-voltage ride-through should be equal to the three-phase fault-clearing time on the network. The zero-voltage ride-through is up to 9 cycles but may be less depending on the clearing time. This should be made explicit in any requirement.

Recommendation: Transmission-interconnected VER should not have any active anti-islanding functions enabled unless these functions are properly coordinated with all applicable stakeholders so that the functions do not detract from bulk transmission system transient or dynamic stability.

Recommendation: It is not suggested that a NERC-wide requirement be mandated for riding through a rate-of-frequency change. If a standard is desired by individual operators, a rate-of-change ride-through requirement of 2.5 Hz/s appears adequate. (This rate of frequency change is stipulated in the current draft of PRC-024). There may be some Regional Entity differences where at least 4.0 Hz/s is required.

Recommendation: Disturbance performance requirements, including PRC-024, should indicate the maximum level of transmission contingency (e.g., N-1-1) for which a plant should be required to ride through.

Response: PRC-024 needs a standards review.

Recommendation: Disturbance performance requirements, such as PRC-024, should clearly define any requirement for repeated disturbances.

Response: The NERC TPL-001-4 standard requires N-1-1 (P6 two overlapping singles) to be studied with system adjustments allowed. However, the time duration between the singles is not clearly defined: it could be 5 minutes or 30 minutes, for example, which has an impact on equipment ride-through capability.

Recommendation: PRC-024 should define the performance required during and after disturbances and should make clear and unambiguous statements as to what remaining “connected” entails. It is not recommended that active power be required during a voltage disturbance unless there is a reliability concern. The sourcing of reactive power during a severe fault should instead be given priority over real power delivery, and the magnitude of reactive power should be consistent with pre-fault reactive power capability. The capability to supply reactive current during a fault varies with technology and product offerings, and so a market to incentivize, but not require, the increased sourcing of reactive current during a voltage dip is recommended.

Transition Category	Planning – Technical Guidelines

Power Recovery after Blackout Recommendation: Recovery after Blackout: It is reasonable to clarify the restart expectations of a generator facility following a disturbance. In some cases, the Transmission Operator provides a signal to the facility that prohibits automatic restarting after a severe grid event. FAC-001 could be modified to include a facility connection requirement to address generator facility restarting.

Response: EOP-008 already covers system restoration, and interconnection agreements cover restarting of generating facilities after faults on the system or a blackout. There is no need or technical basis for FAC-001 to be revised. The Task 1-3 team recommends that NERC provide some technical guidance for industry.

Transition Category	Planning – Technical Guidelines

Recommendation to Require Capability to Limit Rate of Increase of Power Output: Variable generation plants should be required to have the capability to limit the rate of power increase. This type of up-ramp rate control capability has been required in some other systems. This function should include the ability to be enabled and disabled by instruction from the Transmission Operator, Balancing Authority, or Reliability Coordinator.

Recommendation: Plants must be able to accept commands to enable pre-selected ramp-rate limits. Plants should be designed with recognition that ramp-rate limits should not be required under all operating conditions. It should not be required that variable generation plants limit power decreases due to declines in wind speed or solar irradiation (i.e., down-ramp-rate limits). However, limits on decreases in power output due to other reasons, including curtailment commands, shut-down sequences, and responses to market conditions, can be reasonably required.

Response: The team recommends NERC, through its Planning Committee and the System Analysis and Modeling Subcommittee (SAMS), to provide a technical guideline document for the industry.

Transition Category	Planning – Technical Guidelines

Recommendation: Encourage or mandate reduction of active power in response to high frequencies: Variable generation plants should be encouraged to provide over-frequency droop response of similar character to that of other synchronous machine governors.

Recommendation: Consider requiring the capability to provide increase of active power for low frequencies: Variable generation plants should not be required to provide governor-like frequency response for low frequency under normal operating conditions. This is consistent with any conventional power plant operating at full throttle output (i.e., valves wide open). However, encouraging VGs to have the capability to provide this response, and then establish rules and possibly compensation for when such controls would be enabled, could be considered. This presumably would be a rare occurrence, as the economic penalty associated with enabling these controls is high.

Recommendation: Consider requiring inertial response in near future: With the exception of Hydro-Québec, inertial response characteristics have not been specified in grid codes or interconnection requirements for wind plants. Furthermore, language describing this functionality in technology-neutral terms and subject to the physical reality of variable generation facilities is not presently available. Requiring this function in the future as the technology matures and as grid operators and reliability organizations learn more about the need for inertial response characteristics from wind plants should be evaluated further. However, incremental costs should be carefully weighed against alternatives on both the supply and demand side for providing this important reliability service.

Response: ERSTF *Measures Framework* report will consider some of these concerns, and the team, along with the IVGTF leads, recommends that NERC (RAPA-RISA) write a technical guideline on frequency response.

Transition Category	Planning – Technical Guidelines

Recommendation on Harmonics and Subsynchronous Interaction: There is no need for NERC to develop interconnection criteria related to SSR/SSI or harmonics at this time. However, it would be prudent for transmission owners and grid operators to: 1) Consider design study reports that assess the harmonic performance of all wind and solar plants, and 2) Until better understanding of the control interactions issue is gained, consider design study reports

that assess the risk, and if necessary mitigation, of wind and solar plants located near series-compensated transmission lines or HVDC terminals.

Transition Category	No Action

Recommendations for Models for Facility Interconnection Studies

Accurate models are required for all generator facilities that are connected to or are planning to connect to the BES (100 kV and higher) regardless of size. Ongoing model revalidation is currently covered by:

- MOD-024-1: Verification of Generator Gross and Net Real Power Capability
- MOD-025-1: Verification of Generator Gross and Net Reactive Power Capability
- MOD-026-1: Verification of Models and Data for Generator Excitation System Functions
- MOD-027-1: Verification of Models and Data for Turbine/Governor and Load Control

The ongoing detailed model validation may evolve to cover generator units or generator facilities 75 MVA or larger. This breakpoint covers at least 80 percent of the currently installed generation in North America and matches the NERC Statement of Compliance Registry Criteria, which is approved by FERC.

Response: This is the current DGR SDT position from the currently posted version of the white paper "4.7.3 MOD-024-1 –Verification of Generation Gross and Net Real Power Capability."

Transition Category	Planning – Technical Guidelines

Recommendation: Summary of Facility Connection Model Grid Code Requirements: Several key features could be recommended for adoption by Transmission Owners.

- Preliminary model data may be used for the initial feasibility study of a variable generator interconnection project.
- The best model available shall be used for the final System Impact Study or Facilities Study. These models can be user-written and require nondisclosure agreements.
- The detailed dynamic model must be accurate over the frequency range of 0.1 to 5 Hz. Time constants in the model should not be less than 5 ms.
- The detailed dynamics model must have been validated against a physical or type test.
- Verification of detailed model performance should be confirmed during commissioning to the extent possible. The following tests shall be performed: 1) primary/secondary voltage control, 2) low-voltage and high-voltage ride-through, 3) power factor/reactive power capability, 4) Power Ramping and Power Curtailment.
- Verification of the non-proprietary model accuracy may be performed by simulation tests compared with the detailed model performance.
- At the end of the commissioning tests, the Generator Owner shall provide a verified detailed model and a non-proprietary model, ideally in IEEE, IEC, or other approved format, for ongoing Regional Entity studies such as TPL-001.

Response: IVGTF T1-3 response: There is minimal support to make FAC-001 prescriptive. The above recommendations can be documented in a technical guidance document for industry.

Transition Category	Planning – Technical Guidelines

Communications between Variable Generation Plants and Grid Operators Recommendation: The Task 1-3 project team recommends that the basic requirements for communications and control between grid operators and variable generation plants be based on existing policy for conventional generators.

- Variable generation plants should send a minimum set of monitoring data to the grid operation via the grid's SCADA network.
- Variable generation plants should receive and execute command signals (power limit, voltage schedule, ramp-rate limit, etc.) sent from the grid operator via the SCADA network.

- Variable generation plants should have trained on-call plant operators who can receive calls from the grid operator 24/7 and immediately execute verbal commands. The plant operators would not need to be located at the plant provided they have secure remote control capability for the plant.

Response: There is minimal support to make FAC-001 prescriptive. The above recommendations can be documented in a technical guidance document for industry.

Transition Category	Operating – Technical Guidelines

Active Power Control Capabilities Recommendations:

- **Require curtailment capability, but avoid requirements for excessively fast response:** Variable generation can respond rapidly to instructions to reduce power output. In many cases response is faster than conventional thermal or hydro generation. However, there have been cases where proposed grid codes have made excessive requirements for speed of step response to a curtailment order. This is technically challenging and should be avoided. A (Δ) 10 percent (%)/s change for rate of response to a step command to reduce power output is reasonable. This rate of response to step instructions should not be confused with deliberate imposition of ramp-rate limits, as discussed next. Active power considerations are not driving reliability requirements at this time. Some conventional generation can reach or even exceed these rates. Most cannot. The project team is not aware of any NERC standards that specify rate of response to re-dispatch commands (of which curtailment is a subset) in this time frame. Typically, plants must respond to economic re-dispatch within minutes. Mechanisms such as markets or other incentives to encourage rapid rate of response from all generating resources should be considered.
- **Require capability to limit rate of increase of power output.**

Response: The ERSTF and IVGTF teams suggest that NERC, through its Operating Committee (OC) and Operating Reliability Subcommittee (ORS), develop an operating practice technical guideline document on active power control capabilities.

Transition Category	Standards Review and/or SAR

Recommendation to NERC Standard FAC-001-0 Modification: Generator facilities smaller than the 75 MVA threshold—especially variable generation facilities—may experience rapid changes in control performance over their lifetimes due to equipment upgrades and replacements. These changes should be captured in updated models. However, substantial modifications on facilities less than 75 MVA may not be captured by the FAC-001 standard or MOD standards. However, substantial modifications on facilities less than 75 MVA may not be captured by the FAC-001 standard or MOD standards.

Modify FAC-001-0 to: "R2: The Transmission Owner's facility connection requirements shall address, but are not limited to, the following items: R2.1.1 Procedures for coordinated joint studies of new or substantially modified facilities and their impacts on the interconnected transmission systems."

Response: NERC, through its Functional Model working group and the Standards Committee, needs to examine the present definitions for the BPS and consider modifications that could include smaller generation facilities.

Transition Category	Standards Review and/or SAR

Recommendation to NERC Standard FAC-001-0 Modification: The following statement should be added to the FAC-001-0 standard as an appendix for clarifying R3.1.17: "Preliminary or approximate power flow and dynamic models may be adequate for the preliminary assessment of interconnection impacts, or to represent existing and proposed projects that are not in the immediate electrical vicinity of the facility being studied. However, detailed dynamic (and possibly transient) models for the specific equipment may be needed for the System Impact Study and Facilities Study to represent the facility and other equipment in the electrical vicinity. Generic non-proprietary publicly available models are more appropriate for the NERC model building process covered by existing MOD standards, although validated generic models with specifically tuned parameters may be adequate for interconnection studies. The models for interconnection studies must be acceptable to the Transmission Owner in terms of simulation platform, usability, documentation, and performance."

Task 1-4 Flexibility Requirements and Metrics for Variable Generation: Implications for Planning Studies	
Transition Category	ERSTF

Recommendations:

- Probabilistic planning methods being developed in NERC's IVGTF Task 1-6 will be a vital improvement to assess required flexibility.
- As part of developing the Variable Generation Reference Guide (Task 3-1 Recommendation Report), a set of best planning practices to design systems with sufficient system flexibility to accommodate targeted levels of variable generation should be documented.

Transition Category	Data Collection & ERSTF

NERC Reliability Metrics Working Group (RMWG) Agreed-Upon Metrics Recommendations:

- Develop and collect metrics that measure flexibility needs for variable generation. For example, calculating a set of ramp and intensity metrics can provide insights on flexibility trends.
- Compare projected and actual annual energy levels from variable generation.
- Measure variable generation performance factors such as capacity factors and peak coincidence factors.
- Conduct planning studies to account for this increased flexibility requirement.

Transition Category	Planning – Technical Guidelines

Recommendations:

- Develop production cost models, including transmission models, to assess the interaction between the dispatchability of wind and transmission.
- Extend use of statistical analysis of hourly and sub-hourly wind plant output and net-load data (mainly simulated but some historical data was used where available) to ensure that production cost models adequately capture ramp rate and minimum generation constraints and account for regulation requirements.
- Wind forecast error models to account for operational impacts caused by the uncertain nature of variable generation (wind forecasting is covered by Task 2-1).

Task 1-5 Potential Reliability Impacts of Emerging Flexible Resources	
Transition Category	Research and Development

Recommendation: The electric power industry should pursue research and development activities to assess the flexibility needs for the regional and interregional systems of North America as well as evaluate the benefits of flexible resources and technologies (i.e., Demand Response (DR), electric and thermal energy storage, and plug-in electric vehicles (PEVs)) on their respective systems.

Transition Category	No Action

Recommendation: If all resources are provided equal opportunity and information as to power system reliability needs, markets and commercial viability should determine what resources provide specific reliability functions to the grid.

Transition Category	No Action

Recommendation: If the emerging flexible resources addressed in this report (i.e., Demand Response (DR), electric and thermal energy storage, and PEVs) are to play a significant role in providing the additional flexibility needed to

accommodate high levels of variable generation, the barriers and limitations identified in this report must be addressed.	
Transition Category	Research and Development
Recommendation for Technical Development: Develop an operational infrastructure that provides visibility and control (direct or indirect) of distributed resources such as Demand Response and PEVs: 1) Appropriate communication systems and methods of aggregating the resources into larger resource blocks are likely needed. System operators will need to understand the operational state and energy capacity available to the system in real time via full integration into energy management systems (EMS) and market operation systems. This development includes technical, administrative, and commercial aspects. 2) Aggregation of the resources into larger blocks will require developing the administrative processes to aggregate and bid the blocks of resources into the appropriate markets.	
Transition Category	No Action
Recommendation for Market Development: Adjust market rules that unnecessarily limit the types of resources for providing specific reliability functions. Some markets specifically designate some classes of resources as unable to participate in supplying some services: 1) Market rules should be adjusted to allow a variety of resource types to participate within stated performance specifications. Resource developers can then determine whether they can package any resource type to meet the performance criteria in an economically viable manner. Thus, market rules should be reviewed in all regions to remove any unnecessary restrictions. 2) The development of a tariff for PEV owners that would discourages charging during peak hours and encourages charging during off-peak hours. 3) For commercial purposes, incent PEVs to charge at appropriate times (off peak).	
Transition Category	Definition Revisions/Addition By NERC
Recommendation: Adjust regional or federal Reliability Standards that limit resources that can be used for providing specific reliability functions. Similar to market rules, Reliability Standards may also limit certain resource groups from providing some reliability functions: Reliability Standards may also limit certain resource groups from providing some reliability functions. For example, the NERC Glossary definition of spinning reserve references “unloaded generation,” which has been interpreted as prohibiting load from participating. As with market rules, federal and regional reliability standards should be adjusted, if necessary, to allow all resource groups to participate in providing reliability services within specified performance criteria.	
Transition Category	NERC Training & Education
Recommendation: Advances and enhancements that inform all resources of the value of needed flexibility services and incent desired response while discouraging undesired response will be needed; for example, the development of a tariff for PEV owners that would discourage charging during peak hours and encourage charging during off-peak hours.	
Task 1-6 Probabilistic Methods	
Transition Category	Research & Development
Recommendations: • **Reserves:** The level of specific reserves needed for VG integration is broadly understood; however, specific methods have not been rigorously tested and compared. The application of stochastic methods appears promising but needs validation and acceptance if the methods are to be successfully used. • **Dispatch:** There is emerging work on probabilistic methods to dispatch conventional generation to minimize cost and maintain reliability in the presence of high levels of VG; however, there is a gap between academic work and practice as a result of more limited experience with high levels of VG.	

- **Commitment:** There has been considerable interest in stochastic unit commitment. Methods and approaches vary, and most of this work resides in the academic/research domain. Collaboration to evolve and move these methods into actual practice, when appropriate, is needed.
- **Maintenance:** Maintenance scheduling may be more difficult in market regions where there is limited central authority to coordinate scheduled maintenance, and high levels of VG will likely have a significant influence. Methods to quantify the risk of both capacity shortfalls and flexibility shortfalls can be developed and tested in industry.
- **Generation planning:** There have been new methods developed to begin quantifying flexibility needs and risks of insufficient flexibility within generation expansion planning algorithms, so that results balance investment in VG with investments in technologies providing the flexibility that VG requires. There is room for improvement in these methods and a need to evolve and move these approaches from the research community to industry practice.

Transition Category	Planning – Technical Guidelines

Recommendations:

- Transmission planning: There is evidence that stochastic approaches to transmission planning may yield more robust solutions; combining such methods with co-optimization of generation and planning decisions is particularly appealing, but computationally challenging. However, these methods are new/emerging, and additional research and deployment of such methods may be useful.
- Grow appreciation for the ways in which the future power system will change. Variable generation is a catalyst for this change in viewpoint, but it is certainly not the only driver toward a different future system that challenges some of our traditional assumptions and practices.
- Work to develop and demonstrate efficient probabilistic techniques and solutions that are capable of addressing full-scale industry problems.

Transition Category	NERC Training & Education

Recommendation: Improve the understanding of probabilistic methods within the industry. The research community needs to work more closely with the industry to clearly demonstrate the benefits of probabilistic methods. The industry needs to clearly communicate shortcomings in deterministic methods and areas that probabilistic methods can be most fruitful. Cooperative efforts of the research and industry communities are needed to overcome the challenges in terms of both understanding and demonstration.

Transition Category	NERC Data Collection

Recommendation: More and better data are needed to allow the research and demonstrations to be meaningful and realistic—from real power systems, from VG resources, and for future VG deployment scenarios. Collecting and maintaining large data sets can be expensive; however, stochastic methods generally require data that may not currently be readily available. We encourage industry discussion of the trade-offs and costs vs. benefits of collecting data that could help inform stochastic methods and the more rigorous assessments of various risks associated with power system planning and operations with high levels of VG.

Transition Category	Planning – Technical Guidelines

Recommendation: Because we envision a significant increase in the development and application of stochastic methods to help analyze the impacts of VG, we recommend that NERC perform a bi-annual assessment of development in this area. The IVGTF would be an appropriate home for this work.

Task 1-7 Performance of Distributed Energy Resources During and After System Disturbance Voltage and Frequency Ride-Through Requirements

Transition Category	NERC Reliability Assessment

Recommendation: In the short term, NERC should engage in current efforts to revise DER interconnection standards by providing information; supporting the efforts of IEEE with transmission reliability subject matter experts; raising industry, regulator, and policy maker awareness; and encouraging the consideration of the explicit VRT and FRT for DERs.

Transition Category	NERC Staff – External Coordination Activity

Recommendations for IEEE Standard:

- The initial focus should be on potential ways to adopt minimum-tolerance thresholds for VRT and FRT in IEEE Standard 1547 while balancing against other important distribution issues such as safety and protection/coordination.
- The task force also offers general guidelines on VRT and FRT specifications for distributed VERs and other DERs, for consideration in the P1547a process or future IEEE Standard 1547 revisions.

Task 1-8 Potential Bulk System Reliability Impacts of Distributed Resources

Transition Category	Research & Development

Recommendation: NERC, state regulators, and/or industry should develop an analytical basis for understanding the potential magnitude of adverse reliability impacts and how that magnitude changes with penetration of DERs and system configuration/composition.

Transition Category	NERC Training & Education

Recommendation: As many DER issues may be beyond the scope of NERC's authority, and since it may be feasible to address these issues through non-NERC avenues (such as through market rules, vertically integrated operations, or state programs), it is recommended that NERC work with the affected entities in the different regions, including state agencies having jurisdiction over DER, RTOs, and vertically integrated utilities, to develop appropriate guidelines, practices, and requirements to address issues impacting the reliability of the BES resulting from DERs.

Transition Category	Planning – Technical Guidelines

Recommendation: Based in part on the analytical results and the broad experience of generation, transmission, and distribution owners and operators, specific recommendations for changes to operating and planning practices, state programs, and pertinent NERC Reliability Standards should be developed.

Task 2-1 Variable Generation Power Forecasting for Operations

Transition Category	Operating – Technical Guidelines

Recommendation: Wind and solar plants require real-time meteorological and electrical data through SCADA systems using standard communication protocols for use in forecasting and system operation, including power, availability, curtailment, and meteorological data.

Response: FERC Order 764 has largely addressed this issue for wind. A technical guideline may be appropriate to recommend similar measures for solar.

Transition Category	Operating – Technical Guidelines

Recommendation: Wind plant output forecasts, often several of them, should be adopted as standard system and market operation tools for economic operation and system reliability purposes. Multiple types of forecasts and forecast optimizations are practical and important:

- Clarity around how a particular forecast will be used must be clearly defined for both the provider and user of a forecast product.
- Given the value of incrementally better forecasts, system operators should consider a multiple forecasting provider model (aka, the German approach) rather than using a single external or internal forecasting service.

Transition Category	ERSTF

Recommendation: Wind plant output forecasts, often several of them, should be adopted as standard system and market operation tools for economic operation and system reliability purposes. Multiple types of forecasts and forecast optimizations are practical and important:

- A ramp forecast is possible and useful, but may need to be optimized for a different use than the conventional power forecast. The "chance of ramp" indication is valuable even if it is not perfect. In fact, the complexity of weather events guarantees that ramp forecasts will not be perfect.
- It may be beneficial to tune the wind power forecast to take into account the state of system. Morning load pickups and evening load drop-offs may require better knowledge of the likelihood of wind ramps, and should be investigated by the system operator.

Transition Category	Operating – Technical Guidelines

Forecasts Recommendations:

- Initial use of aggregate, regional, and individual wind plant forecasts by reliability coordinators in the control room is a logical first step.
- Use of the forecast in unit commitment planning is very important. Adjusting to clear the day-ahead market with a combined load and wind power forecast (rather than ignoring the wind) would improve both the economics and reliability of system operation.

Transition Category	Research and Development

Forecasts Recommendation: Probabilistic methods are increasingly important, and the uncertainty distributions around all forecasts (including but not limited to the variable generation power forecasts) should be addressed more explicitly. As a minimum, the use of a "chance of ramp" forecast probability should be used to identify whether or not additional reserves are needed.

Transition Category	ERSTF

Recommendation: There are overwhelming benefits from adjusting operating rules and practices, and these adjustments may have more benefit to both reliability and economic operations than the forecasting alone.

- Sub-hourly markets with sufficient liquidity, or the ability to otherwise dispatch generation closer to real time with sufficient flexibility, can be very effective in addressing the variability and uncertainty of variable generation.

Transition Category	Operating – Technical Guidelines

Recommendation: There are overwhelming benefits from adjusting operating rules and practices, and these adjustments may have more benefit to both reliability and economic operations than the forecasting alone:

- Incorporating the variable generation power forecast into unit commitment is important for economical and reliable operation.

Transition Category	No Action

Recommendations: There are overwhelming benefits from adjusting operating rules and practices, and these adjustments may have more benefit to both reliability and economic operations than the forecasting alone:

- Negative price offers for resources should be included in markets that do not yet offer this capability to help maintain reliable and economical operation.
- The benefits of larger balancing areas with fewer transmission constraints are overwhelming. Resolving transmission constraints is critical because larger balancing areas lose many of the benefits associated with size if constraints are in play. Areas with sufficient transmission capacity are exploring how to achieve the benefits of larger areas through direct balancing area consolidation or through efforts at "virtual consolidation" where separate balancing areas work together on particular issues. Smaller areas, such as island systems, will have special challenges that require additional control. Larger operating areas, with minimal transmission constraints and diverse variable generation assets, should be capable of dealing with the expected levels of variable generation.

Transition Category	Research and Development

Recommendations: Ongoing innovation is needed, with both government and private industry involvement. Innovation is needed to continue to improve forecasting products. This requires multiple cooperating players:

- Government R&D and forecasting centers for improved data systems, model development, and general operational weather deliverables.
- A vibrant, competitive forecasting service community to assist in the R&D, applications, and services for business-augmented use of operating data with forecasting products.
- Developers of system operating tools and methods, both in private companies and in the system operator organizations, to deal with the true variability and forecast probability distributions that are implicit to our real-world systems, system operators, and stakeholders.

Transition Category	No Action

NERC should enhance its Reliability Standards by organizing Standard Authorization Requests or supporting existing standard development processes including but not limited to the following standards that require potential changes:

Response:

- **TOP-002 (Normal Operations Planning)**: Project 2014-03 is revising a significant number of standards in the TOP and IRO families. In support of the proposed revisions, retirement of TOP-002-2.1b Standard, and the approval of TOP-002-4 standard has been requested. The currently proposed draft of TOP-002-4 includes proposed R1, which states, "Each Transmission Operator shall have an Operational Planning Analysis that will allow it to assess whether its planned operations for the next day within its Transmission Operator Area will exceed any of its System Operating Limits (SOLs)."" Further, the currently proposed revision of TOP-003-3 includes the following proposed revision of the term as follows: "Operational Planning Analysis – An evaluation of projected system conditions to assess anticipated (pre-Contingency) and potential (post-Contingency) conditions for next-day operations. The evaluation shall reflect inputs including, but not limited to, load forecasts; generation output levels; Interchange; known Protection System and Special Protection System status or degradation; Transmission outages; generator outages; Facility Ratings; and identified phase angle and equipment limitations. (Operational Planning Analysis may be provided through internal systems or through contracted services.)" The use of the defined term "Operational Planning Analysis" in the currently proposed draft of TOP-002-4 allows for the inclusion of load forecasting as well as variable generation data for use in operations planning and analysis.
- **TOP-006 (Monitoring System Conditions)** Requirement 1.1: Currently proposed draft TOP-003-3, R5 directs the Generator Owner to respond to a request for specific data rather than initiate the transfer of data, which will allow the applicable registered entity requesting the data to determine the appropriate input required to meet their monitoring responsibility.
- **COM-002 (Communication and Coordination):** Standard is revised; the new language is sufficient.

- **IRO-005 (Reliability Coordination – Current-Day Operations):** The Project 2014-02 Standards Applicability for Dispersed Generation Resources Standards Drafting Team performed a review of all standards that apply to Generation Owners and/or Generator Operators, determined how each standard requirement should be appropriately applied to dispersed generation resources, and categorized them as follows:
  - The existing standard language was appropriate when applied to dispersed generating resources and does not need to be addressed;
  - The existing standard language was appropriate when applied to dispersed generating resources, but additional NERC guidance documentation is needed to clarify how to implement the requirements for dispersed generating resources; and
  - Detail is provided in a white paper that is posted on the website for Project 2014-02. It was developed by the drafting team with the intent that the drafting team will modify this document over the course of Project 2014-02 to document the team's rationale and technical justification for each standard until the work of the Drafting Team is complete.

Transition Category	Operating – Technical Guidelines

Recommendation: NERC should enhance its Reliability Standards by organizing Standard Authorization Requests or supporting existing Standard development processes including but not limited to the following standards that require potential changes:

- FAC-001 (Facility Connection Requirements) – (Section R2): The currently proposed draft of FAC-002-2 addresses the responsibilities of the Generator Owner by stating, "Each Generator Owner seeking to interconnect new, or materially modify existing, generation Facilities shall coordinate and cooperate on studies with its Transmission Planner or Planning Coordinator . . . " This requirement is sufficiently broad to facilitate the Transmission Owner's requests for specific information, cooperation, and collaboration from the Generation Owner.

Recommendation: Investigated developing a new NERC Reliability Standard that provides for regional forecasts and local wind/solar facility wind forecasts to schedule variable generation.

Transition Category	ERSTF

Recommendation: NERC should enhance its Reliability Standards by organizing Standard Authorization Requests or supporting existing standard development processes including but not limited to the following standards that require potential changes:

- **BAL-002 (Disturbance Control Performance**) – Requirement 3.1: The ERSTF Ramp and Frequency Support subgroups should consider the value of treating unexpectedly sudden changes of wind and solar power as "credible contingency" events under the BAL-002 standard. If the change in wind or solar power was not well forecast, the ERSTF should also consider whether slower ramps (not just "sudden loss" events) should be included as contingency events.

Task 2-2 Reliability Considerations for BA Communications with Increased Variable Generation

Transition Category	No Action

Recommendation: Transmission Operator would list their specific requirements not only for generation connected to the transmission system but also any generation in the footprint that is within the area operated by the Transmission area that will impact the operation of the Balancing Authority and Bulk Electric Transmission System.

Response: FAC-001-1, subject to enforcement, includes as R1 the requirement, "The Transmission Owner shall document, maintain, and publish Facility connection requirements to ensure compliance with NERC Reliability Standards and applicable Regional Entity, subregional, Power Pool, and individual Transmission Owner planning criteria and Facility connection requirements."

Requirements R2 and R3 of this standard apply to any GO that has an external party applying for interconnection to the GO's existing Facility in order to connect to the transmission system. This scenario is uncommon and there is no

precedent for applicability of this standard to dispersed-power-producing resources known to the SDT. Current practice primarily includes the GO stating that they will comply with the standard if this scenario is ever realized. This standard allows the GO to specify the conditions that must be met for the interconnection of the third party, thus providing inherent flexibility to tailor the requirements specifically for the unique needs of the Facility. Therefore, the applicability of FAC-001 does not need to be changed for dispersed-power-producing resources.

Transition Category	Data Collection

Data and communication capabilities should be provided to the BA by all generation operating in the BA that has an impact on the reliability of the BES.

- Net and Gross MW and MVAR output
- Meteorological data (wind speed, wind direction, temperature, and barometric pressure)
- High- and Low-Sustained Limit
- Normal and emergency ramp-rate capability
- Turbine availability
- Breaker Status
- Modeling data (static information)
  - Tower height
  - Relay settings (including UFR settings)
  - Type of turbines
- Voice circuit
  - Available communication to plant operator
  - Communication to address real-time operational issues
- Set point and curtailment communication (market areas)

Transition Category	No Action

Recommendation: COM-002 – Consider applying the standard to all generation 10 MW or greater. This improvement in communication will not only improve data communication but also require the GOP to be available to address real-time operational issues. This can be accomplished with manned resources or remote control and monitoring of the facilities.

Recommendation: PRC-001 – Under R3, make this requirement applicable to facilities 10 MW or greater. This will ensure that the necessary relay coordination has taken place to reduce the reliability impact of unexpected relay operation, specifically operation of under- and overfrequency relays. The generation should be set lower than the Underfrequency Load Shedding relays in the region to ensure generation tripping does not compound underfrequency operation similar to the European event.

Response:

1. This would conflict with the effective BES definition, which is comprised of the following: “Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This does not include facilities used in the local distribution of electric energy.

   Inclusions:

   Inclusion 1: Transformers with the primary terminal and at least one secondary terminal operated at 100 kV or higher unless excluded by application of Exclusion E1 or E3.

   Inclusion 2: Generating resource(s) including the generator terminals through the high side of the step-up transformer(s) connected at a voltage of 100 kV or above with:

   a) Gross individual nameplate rating greater than 20 MVA; or,

   b) Gross plant/facility aggregate nameplate rating greater than 75 MVA.

   Inclusion 3: Blackstart Resources identified in the Transmission Operator’s restoration plan.

Inclusion 4: Dispersed-power-producing resources that aggregate to a total capacity greater than 75 MVA (gross nameplate rating), and that are connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage of 100 kV or above.

Thus, the facilities designated as BES are:

a. The individual resources, and

2. The system designed primarily for delivering capacity from the point where those resources aggregate to greater than 75 MVA to a common point of connection at a voltage of 100 kV or above. "Further, even when the conflict with the effective Bulk Electric System definition is disregarded, this recommendation appears to be adequately addressed through the structure of TOP-003-3, which provides a means by which the Transmission Operator may obligate Generator Operator availability to address real time operational issues if necessary by way of a documented specification. TOP-003-3 R1. states: "Each Transmission Operator shall maintain a documented specification for the data necessary for it to perform its Operational Planning Analyses, Real-time monitoring, and Real-time Assessments," and further requires as R1. Part 1.1-1.4: the data and information needed; data precocity; and deadlines for data provision. TOP-003-3 R3 states, "Each Transmission Operator shall distribute its data specification to entities that have data required by the Transmission Operator's Operational Planning Analyses, Real-time monitoring, and Real-time Assessment." TOP-003-3 R5. States, "Each . . . Generator Operator . . . receiving a data specification in Requirement R3 . . . shall satisfy the obligations of the documented specifications." Therefore, compliance with the standard will generate a documented specification created by the Transmission Operator that will specify the precocity and deadlines for data provision (TOP-003-3 R1. Part 1.1-1.4), distribution of such documented specification to the Generator Operator (TOP-003-3 R3.), who is then required to satisfy the obligations of the documented specifications for data (TOP-003-3 R5). The structure of TOP-003-3 is such that the Transmission Operator may obligate Generator Operator availability to address real-time operational issues if necessary through the documented specification.
3. The Project 2014-02 Standards Applicability for Dispersed Generation Resources Standards Drafting Team performed a review of all standards that apply to Generation Owners and/or Generator Operators and determined how each standard requirement should be appropriately applied to dispersed generation resources and categorized them as follows:

• The existing standard language was appropriate when applied to dispersed generating resources and does not need to be addressed; Thee existing standard language was appropriate when applied to dispersed generating resources but additional NERC guidance documentation is needed to clarify how to implement the requirements for dispersed generating resources; and

• The existing standard language was appropriate when applied to dispersed generating resources but additional NERC guidance documentation is needed to clarify how to implement the requirements for dispersed generating resources; and

• The existing standard language needs to be modified in order to account for the unique characteristics of dispersed generation resources. This could be accomplished through the applicability section of the standard in most cases or, if required, through changes to the individual requirements.

The COM standards focus on communication between the RC, BAs, TOPs, and GOPs. The only requirements in any of the current or future enforceable standards that apply to the GOP are clearly intended to apply to the individual GOP registered functional entity (i.e., requires communication between GOPs, TOPs, BAs, and RCs), not the constituent Elements it operates. Consequently, there is no need to differentiate the GOP's obligation for dispersed-power-producing resources from any other resources. Therefore, the applicability of the COM-001-2, COM-002-2a, and COM-002-4 standards that were reviewed do not need to be changed for dispersed-power-producing resources.

PRC-001-1.1 — System Protection Coordination: Requirement R1 requires GOPs to be familiar with the purpose and limitations of Protection System schemes applied in their area. The recently approved changes to the BES definition extend the applicability of this requirement. Often this familiarity is provided to GOP personnel through training on the basic concepts of relay protection and how it is utilized. The basic relaying concepts utilized in protection on the aggregating equipment at a dispersed generation site typically will not vary significantly from the concepts used in Protection Systems on individual generating units.

Requirement R2 requires that GOPs report protective relay or equipment failures that reduce system reliability. Protective System failures occurring within a single individual generating unit at a dispersed-power-producing resource will not have any impact on overall system reliability and thus it should not be necessary for GOPs to report these failures to their TOPs and host BAs. Only failures of Protection Systems on aggregating equipment have the potential to impact BPS reliability and may require notification. When interpreted as stated above, no related changes should be required to the existing PRC-001-1 standard, as the BES definition changes do not have an impact on these requirements. Requirement R3 requires GOPs to coordinate new protective systems. The coordination of new protective relay schemes and changes to existing protective relay schemes should occur to aggregating equipment protection only if a lack of coordination could cause unintended operation or non-operation of an interconnected entity's protection, thus potentially having an adverse impact to the BPS.

Existing industry practice is to share/coordinate the protective relay settings on the point of interconnect (e.g., generator leads, radial generator tie line, etc.) and potentially the main step-up transformer, but not operating (collection) buses, collection feeder, or individual generator protection schemes, as these Protection Systems do not directly coordinate with an interconnected utility's own Protection Systems. Relay protection functions such as under- and overfrequency and under- and overvoltage changes are independent of the interconnected utility's protective relay settings. The setting criteria are defined in PRC-024.

Requirement R5 requires GOPs to coordinate changes in generation, transmission, load, or operating conditions that could require changes in the Protection Systems of others. A GOP of a dispersed generation resource should be required to notify its TOP of changes to generation, transmission, load, or operating conditions on an aggregate Facility level.

Project 2007-06 – System Protection Coordination and Project 2014-03 – Revisions to TOP and IRO standards include various aspects of this standard or address certain requirements in other standards.

For these reasons, the DGR SDT coordinated with the other SDTs currently reviewing this standard and recommended revisions to R3.1 to indicate that coordination by a GOP with their TOP and host BA of new protection systems or changes to protection systems on individual generating units of dispersed-power-producing resources is not required.

Transition Category	No Action

Recommendation: All generators 10 MW or greater within a BA regardless of interconnection point shall provide:

- Breaker status to the BA/TOP (FAC-001)
- Current MW and MVAR output (FAC-001)
- Voice circuit for communication of real-time instruction (COM-002)
  - Remote control of resources is adequate but should be capable of handling real-time operational issues.
- Coordination of relay settings, specifically under-frequency coordination (FAC-001)

Response:

Mandating how system impact and facilities studies are completed is not appropriate and should not be part of a Reliability Standard. This level of prescriptiveness goes against the results-based approach for standards. FAC-001 was just revised and the technical experts on the SDT and stakeholders did not agree that this level of prescriptiveness was appropriate. Also, this suggestion inappropriately goes below the BES threshold.

Transition Category	No Action

Recommendation: The following should also be required for all generators 10 MW or greater within a BA regardless of interconnection point, if a significant impact has been identified in an interconnection study:

- Resource schedules with outage information (FAC-001)
- Meteorological data for forecasting (FAC-001)
- Availability (FAC-001)

- High- and Low-Sustained Limit (FAC-001)
  - Including high-wind cutout
  - Temperature limitations
  - Any other operational restrictions

Response: These requirements have already been addressed by FERC Order 764, which requires such dynamic and static data for doing wind power forecasting. Mandating how system impact and facilities studies are completed is not appropriate and should not be part of a Reliability Standard. This level of prescriptiveness goes against the results-based approach for Standards. FAC-001 was just revised and the technical experts on the SDT and stakeholders did not agree that this level of prescriptiveness was appropriate. Also, this suggestion inappropriately goes below the BES threshold.

Transition Category	No Action

FAC-001: Transmission Operator would list their specific requirements not only for generation connected to the transmission system but also any generation in the footprint that is within the area operated by the Transmission area that will impact the operation of the Balancing Authority and Bulk Electric Transmission System.

Response: Mandating how system impact and facilities studies are completed is not appropriate and should not be part of a Reliability Standard. This level of prescriptiveness goes against the results-based approach for standards. FAC-001 was just revised and the technical experts on the SDT and stakeholders did not agree that this level of prescriptiveness was appropriate.

Transition Category	No Action

TOP-001: Under R3, require all generation facilities 10 MW or greater to comply with reliability directives from the Balancing Authority or the Transmission Operator. Under R7, all generation facilities 10 MW or greater provide notice to the Balancing Authority and the Transmission Operator before removing generation facilities from service to reduce the reliability impact to the system.

TOP-002-2b: Under R3, require all generation facilities 10 MW or greater to provide current, next-day, and seasonal operations with the host Balancing Authority and Transmission Provider. This will improve the reliability studies of the BES.

TOP-003-1: For generation facilities 10 MW or greater, require outage coordination of generation facilities including telemetering equipment and voltage regulation equipment so that interconnected operations are coordinated between Balancing Authorities, Transmission Operators, and Reliability Coordinators.

Response: The Project 2014-02 Standards Applicability for Dispersed Generation Resources Standards Drafting Team performed a review of all standards that apply to Generation Owners and/or Generator Operators and determined how each standard requirement should be appropriately applied to dispersed generation resources. They are categorized as follows:

- The existing standard language was appropriate when applied to dispersed generating resources and does not need to be addressed.
- The existing standard language was appropriate when applied to dispersed generating resources but additional NERC guidance documentation is needed to clarify how to implement the requirements for dispersed generating resources.
- The existing standard language needs to be modified in order to account for the unique characteristics of dispersed generation resources. This could be accomplished through the applicability section of the standard in most cases or, if required, through changes to the individual requirements.

Detail is provided in a white paper posted on the website for Project 2014-02. It was developed by the drafting team with the intent that the team will modify this document over the course of Project 2014-02 to document the Drafting Team's rationale and technical justification for each standard until the work of the drafting team is complete.

Task 2-3 Ancillary Services and Balancing Authority Area Solutions to Integrating Variable Generation

Transition Category	Operating – Technical Guidelines
Recommendation: Each region or reserve-sharing group should permit Contingency Reserve deployment under imbalance energy circumstances made more likely with the increasing penetration of renewables.	
Transition Category	Operating – Technical Guidelines
Recommendation: The task team recommends that the generator interconnection requirements be modified to require this dispatchable control capability interfaced with the grid operator for all new variable generation resource developments.	
Transition Category	Operating – Technical Guidelines
Recommendation: Regional market operators and other grid operating entities should develop the ability to consider transmission service by prioritizing variable resources when allocating curtailment responsibility to variable output resources during reliability-limited operating conditions.	
Transition Category	ERSTF
Recommendation: BAL-001-0.1a – Real Power Balancing Control Performance: Increased Balancing Authority collaboration reduces cost overall and is valuable for the integration of variable generation.	
Transition Category	ERSTF
Recommendation: BAL-002-0 – Disturbance Control Performance – The standard drafting team should consider if Contingency Reserves can be used to meet DCS requirements for wind-related events. Reserve calculation procedures should be updated to take into account variable energy resource events, including ramping events that are much slower than the instantaneous contingency events caused by conventional generators and transmission failures. This could impact recommendations for Contingency Reserve Policies, DCS, DCS response time, and DCS recovery time. Alternatively: The current BAL-002 and DCS do not apply to variable energy resource events because they are too slow. There is no need to change BAL-002 due to variable energy resource integration. Balancing Authorities would need to deal with the risk of tail events with their own resources—or with different resources than the current DCS resources. Ultimately, it would be more efficient to mitigate the risk of rare tail events by using pooled reserves, especially in high-penetration scenarios. Action: IVGTF2-3 should collaborate with the standards drafting team to establish another requirement to accommodate variable energy resources and their tail events.	
Transition Category	No Action
Recommendation: IRO-005-3-1a Reliability Coordination — Current-Day Operations – A NERC Reliability Standard is required to communicate variable generation derates due to turbine outage conditions and plans. Currently issues may arise if part of a wind plant is out of service and operators are not aware of the number of turbines unavailable and the duration of the forced or planned outage. **Response:** This recommendation appears to be adequately addressed through the requirements of IRO-010-1a, which is currently subject to enforcement. IRO-010-1a includes as R3 the requirement, "Each Balancing Authority, Generator Owner, Generator Operator, Interchange Authority, Load-Serving Entity, Reliability Coordinator, Transmission Operator, and Transmission Owner shall provide data and information, as specified, to the Reliability Coordinator(s) with which it has a reliability relationship." TOP/IRO project is working on an outage coordination standard as well—IRO-017-1, Outage Coordination.	
Transition Category	No Action

Recommendation: A NERC standard is required to communicate variable generation derates due to turbine outage conditions and plans. Currently issues may arise if part of a wind plant is out of service and operators are not aware of the number of turbines unavailable and the duration of the forced or planned outage.

Response: This recommendation appears to be adequately addressed through the requirements of IRO-010-1a, which is currently subject to enforcement. IRO-010-1a includes as R3 the requirement, "Each Balancing Authority, Generator Owner, Generator Operator, Interchange Authority, Load-serving Entity, Reliability Coordinator, Transmission Operator, and Transmission Owner shall provide data and information, as specified, to the Reliability Coordinator(s) with which it has a reliability relationship."

Transition Category	No Action

Recommendation: TOP-002-2&A Normal Operations Planning The standard should be enhanced to provide guidance on incorporation of variable energy resource events into the planning process.

Response: Project 2014-03 is revising a significant number of standards in the TOP and IRO families. In support of the proposed revisions and retirement of the TOP-002-2.1b standard, the approval of TOP-002-4 has been requested. The currently proposed draft of TOP-002-4 includes proposed R1, which states: "Each Transmission Operator shall have an Operational Planning Analysis that will allow it to assess whether its planned operations for the next day within its Transmission Operator Area will exceed any of its System Operating Limits (SOLs)." Further, the currently proposed revision of TOP-003-3 includes the following proposed revision of the term as follows: "Operational Planning Analysis – An evaluation of projected system conditions to assess anticipated (pre-Contingency) and potential (post-Contingency) conditions for next-day operations. The evaluation shall reflect inputs including, but not limited to, load forecasts; generation output levels; Interchange; known Protection System and Special Protection System status or degradation; Transmission outages; generator outages; Facility Ratings; and identified phase angle and equipment limitations. (Operational Planning Analysis may be provided through internal systems or through contracted services.)"

Transition Category	No Action

Recommendation: TOP-006-1&2 Monitoring System Conditions – Expand R4 to require similar information and prediction of variable generation output:

R4. Each Transmission Operator and Balancing Authority shall have information including weather forecasts and past load, and variable generation patterns are available to predict the system's near-term load and variable generation pattern.

Response: Project 2014-03 is revising a significant number of standards in the TOP and IRO families. In support of the proposed revisions, retirement of TOP-006-2 has been requested, and it has been proposed that requirement R4 of TOP-006-2 transition to proposed draft standard TOP-003-3 R1 & R2. The current proposed draft requires the Transmission Operator to "maintain a documented specification for the data necessary for it to perform its Operational Planning Analysis," and provides the following proposed draft definition: "Operational Planning Analysis – An evaluation of projected system conditions to assess anticipated (pre-Contingency) and potential (post-Contingency) conditions for next-day operations. The evaluation shall reflect inputs including, but not limited to, load forecasts; generation output levels; Interchange; known Protection System and Special Protection System status or degradation; transmission outages; generator outages; Facility Ratings; and identified phase angle and equipment limitations. (Operational Planning Analysis may be provided through internal systems or through contracted services.)" The current proposed draft standard maintains sufficient breadth to allow the Transmission Operator to determine the appropriate data required to perform their Operational Planning Analysis.

Task 2-4 Operating Practices Procedures and Tools	
Transition Category	ERSTF

Recommendation: BAL-002 (Disturbance Control Performance) – The standard may need to be revised to include sudden changes in wind output as "credible contingencies" under the standard. This would ensure that these events are analyzed during reserve calculations. The applicable section of the standard is Requirement 3-1. Additionally,

changes to this standard may need to be addressed with various reserve-sharing groups, many of which have differing rules regarding contingencies.

Transition Category	ERSTF

Recommendation: BAL-005 R-11 – This standard may need to be updated to include the various types of ramp rates that a Balancing Authority may need to use in the scheduled interchange values to calculate ACE. Controlled and uncontrolled ramp rates may need to be included in the analysis since both types can be encountered by variable generation.

Transition Category	ERSTF

Recommendation: COM-002 (Communication and Coordination) – The standard may need to be revised to clarify the meaning of "voice and data links" as used in the standard. To avoid problematic interpretations, the standard should specify that "voice and data links" are those identified in Interconnection Agreements or other governing agreements between the Transmission Operators and the variable generator.

Transition Category	Standard Review and/or SAR

Recommendation: EOP-002 R6 – This standard may need to be updated to reflect curtailment capabilities of various types of generation as one of the possible remedies available to Balancing Authorities. This would ensure that a Balancing Authority has examined various types of remedies that are available when experiencing problems meeting the Control Performance and Disturbance Control Standards.

Response: Good recommendation especially in areas that do not yet have much experience with wind and PV plants. But variable renewables are just one of many technologies. There seems to be a trend for standards to be less specific rather than more. (For example, "The currently proposed draft requirements remove the phrase "monitoring equipment" in favor of the statement "shall monitor," which is applied to each appropriate registered entity and their corresponding responsibility. Employing the phrase "shall monitor" is sufficiently broad to allow the applicable registered entity to determine the appropriate input required to meet their monitoring responsibility.") So if the standard(s) are silent on considering resources like demand response as well as conventional generation, it may not be appropriate to include a specific reference to variable renewables. Perhaps if there is an accompanying guideline or reference document it could be included there.

Transition Category	Standard Review and/or SAR

Recommendation: IRO-004 (Reliability Coordination – Operations Planning) – This standard may need to be updated to reflect forecasting information available to variable generation that is to be made available for next-day studies. Currently, the standard indicates that parties "shall provide information required for system studies, such as critical facility status, load, generation, operating reserve projections, and known Interchange Transactions." Forecasting of variable generation could be added to the list in order to provide an accurate day-ahead study.

Response: This recommendation is directed at the establishment of new requirements. In this case, industry may initiate a SAR if they perceive one is needed.

Transition Category	Standard Review and/or SAR

Recommendation: IRO-005 (Reliability Coordination – Current-Day Operations) – This standard may need to be updated to include active monitoring of forecasting conditions such as weather fronts, icing, and/or high wind conditions by the Reliability Coordinator. The active monitoring would ensure that the Reliability Coordinator is aware of conditions that may arise in the immediate future. This would create consistency with the purpose of the standard, which is: "The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas."

Response: It appears this recommendation is directed at the establishment of new requirements. In this case, industry may initiate a SAR if they perceive one is needed.
This is the current DGR SDT position (from currently posted version of the white paper):

4.6.2 IRO-005 — Reliability Coordination — Current-Day Operations.

The purpose of this standard and its requirements as they relate to GOPs is to ensure that when there is a difference in derived limits, the BES is operated to the most limiting parameter. A difference in derived limits can occur on any Element and, therefore, any limitation of the applicability of this standard may create a reliability gap. There is no need to differentiate applicability to dispersed generation resources from any other GOP resources. Therefore, the applicability of IRO-005 does not need to be changed for dispersed-power-producing resources.

Transition Category	Standard Review and/or SAR

Recommendation: TOP-002 (Normal Operations Planning) – This standard may need to be updated to include a section about forecasting, identifying the data submitted by variable generators as the method of providing generation information to the Transmission Operators. It also needs to recognize forecasting as the best way to estimate generation, albeit subject to some unavoidable uncertainty due to the variability and complexity of weather conditions. This would assist in system operations, especially in day-ahead or hour-ahead operations.

Response:

- Add language that specifically adds variable wind and solar to the list of things that should be considered:

  The currently proposed draft of TOP-002-4 includes proposed R1, which states: "Each Transmission Operator shall have an Operational Planning Analysis that will allow it to assess whether its planned operations for the next day within its Transmission Operator Area will exceed any of its System Operating Limits (SOLs)." Further, the currently proposed revision of TOP-003-3 includes the following proposed revision of the term as follows: "Operational Planning Analysis – An evaluation of projected system conditions to assess anticipated (pre-Contingency) and potential (post-Contingency) conditions for next-day operations. The evaluation shall reflect inputs including, but not limited to, load forecasts; generation output levels; variable renewable generation forecasts; Interchange; known Protection System and Special Protection System status or degradation; Transmission outages; generator outages including variable generation availability; Facility Ratings; and identified phase angle and equipment limitations. (Operational Planning Analysis may be provided through internal systems or through contracted services.)." The use of the defined term "Operational Planning Analysis" in the currently proposed draft of TOP-002-4, allows for the inclusion of load forecasting as well as variable generation data for use in operations planning and analysis.

The term "Operational Planning Analysis" can include variable generation forecasting as well as load forecasting, so no additional wording is required unless "Operational Planning Analysis" is expanded upon in a glossary or footnote or elsewhere, in which case variable generation forecasting should be explicitly listed as a possible component.

Transition Category	Standard Review and/or SAR

Recommendation: TOP-006 (Monitoring System Conditions) – Requirement 5 discusses the use of "monitoring equipment to bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action." This standard may need to be revised to include specific tools such as (1) input from a forecaster, or (2) real-time data from wind and solar plants (e.g., meteorological towers, sonic detection and ranging (SODAR), and real-time turbine telemetry).

Response: It appears this recommendation is directed at the establishment of new requirements. In that case, industry may initiate a SAR if they perceive one is needed.

This is the current DGR SDT position (from currently posted version of the white paper):
4.11.5 TOP-006 — Monitoring System Conditions. The purpose of this standard as it relates to GOPs is to ensure BAs and TOPs know the status of all generation resources available for use as informed by the GOP. It should also be noted that the purpose of this standard is to ensure critical reliability parameters are monitored in real time. It then can be extrapolated that the requirement, "GOP shall inform…," is done by sending dispersed-power-producing resource telemetry in real time and through a digital communication medium, such as an ICCP link or RTU. The SDT feels a modification to the applicability of this requirement is necessary for dispersed-power-producing resources. The SDT

is recommending that this requirement be applied at the aggregate Facility level for dispersed-power-producing resources for the following reasons:

- This is consistent with Inclusion I2 of the revised BES definition, which includes generating units greater than 20 MVA. If removing less than 20 MVA would cause a burden to the BPS, then the threshold for inclusion in the BES would have been less than 20 MVA.
- Routine maintenance is frequently completed on a small portion of the entire Facility (e.g. 2% of the generators are out of service on any given day) as not to have a significant impact on the output capability of the Facility. Additionally, it is not uncommon to have individual generating units at a dispersed-power-producing resource go into failure mode due to internal factors of the equipment, such as hydraulic fluid pressure tolerances, gearbox bearing thermal tolerances, etc. As such, coordinating each individual generating unit outage would burden the TOP without providing an increase in reliability to the interconnected BPS.
- As this standard requires real-time monitoring, this is most likely completed through a digital medium such as an ICCP link or RTU. The data that a dispersed-power resource provides to the BA and TOP in real time should include the aggregate active power output of the Facility, among other telemetry points. These data specifications are usually outlined in interconnection agreements among the parties.

Based on the SDT's technical expertise, BAs and TOPs are informed by the GOP of all generation resources available at the dispersed-power-producing resource at the aggregate Facility level. Traditionally the dispersed-power-producing resources are providing the BA and TOP, at minimum, the following telemetry points in real time: aggregate Real Power, aggregate Reactive Power, and main high-side circuit breaker status. A key aspect of the SDT project is to maintain the status quo, if it is determined not to cause a reliability gap. The SDT has not found or been made aware of a reliability gap that would prompt this team to apply these requirements to any point less than where the dispersed-power-producing resource aggregates and, as such, recommends a modification to the applicability of this requirement for dispersed-power-producing resources.

Transition Category	Standard Authorization Request

NERC Reliability Standards that address the reasonable and effective use of regional forecasts and local wind/solar facility forecasts should be encouraged and used to schedule variable generation to assist in accurate system operation.

Transition Category	Operating – Technical Guidelines

Recommendation: Improving operating practices, procedures, and tools can help reliably integrate variable generation into the power system as well as improve the reliability of the power system in the absence of variable generation.

Transition Category	Enhancement to Modeling

Recommendation: Variability and uncertainty can be reduced through aggregation. Larger aggregations of wind and solar generation are proportionately less variable. Forecast accuracy is also improved for larger wind and solar aggregations. Net variability is also reduced when VERs are aggregated with load, and it is net variability that must be balanced to maintain reliability. The pool of flexible resources (generators and responsive load) increases as the size of the BA increases. Balancing should be conducted over the largest geographic area possible, either through consolidating smaller BAs or through coordinated operations.

Transition Category	ERSTF

Recommendation: The IVGTF suggests that those balancing areas that face significant integration of variable resources consider studying the benefits of sub-hourly scheduling to manage the integration of variable generation. Depending on the current or projected BA system characteristics, assuming sufficient transmission is available, there may be benefits to intra-hour interchange scheduling in the form of reduced ancillary services, more flexibility, and the ability to manage the variability, while still meeting the requirements of NERC's Reliability Standards.

Transition Category	Enhancement to Modeling and Operating – Technical Guidelines

Recommendation: Wind and solar plants should have the capability to send and receive real-time data (meteorological and electrical) through SCADA systems using standard communication protocols for use in forecasting and system operation.

Transition Category	Standard Authorization Request/ERSTF

Recommendation: Wind plant output forecasts, often several of them, should be adopted as standard system and market operation tools for economic operation and system reliability purposes. Ramp forecasts as well as hourly energy forecasts should be considered.

Transition Category	Operating – Technical Guidelines

Recommendation: NERC Regions should consider what control capabilities should be required for new VERs to ensure reliability. Procedures should be developed that limit the use of VER control capabilities to situations where it is required to maintain reliability or when accepting the energy results in excessive costs.

Transition Category	Enhancement to Modeling and Operating – Technical Guidelines

Recommendation: Interconnection requirements for all generation technologies (VER and conventional) need to be designed for anticipated rather than existing conditions, considering aggregate impacts and effects of displacing conventional generation. Interconnection requirements should address control capability, ride-through, inertial response, voltage regulation, etc. It is difficult to modify requirements on existing facilities after the fact.

Transition Category	Operating – Technical Guidelines/ ERSTF

Recommendation: Changes to operating rules and practices are critical:

- Sub-hourly markets with sufficient liquidity, or the ability to otherwise dispatch generation closer to real time with sufficient flexibility, can be very effective in addressing the variability and uncertainty of variable generation.
- Incorporating the variable generation power forecast into unit commitment and dispatch procedures is important for economical and reliable operation.
- More frequent unit commitment can use updated forecasts of VER and load.
- Consider adjusting reserve requirements based on forecast VER output levels. This would allow the reserves to capture the fact that the volatility of wind output is different for different output levels.
- Mechanisms to incent dispatch behavior consistent with system needs. For example, the interaction between variable resources supported by tax credits and renewable energy credits or monetized environmental benefits and a significant proportion of baseload generation with significant minimum generation requirements suggests that the capability to capture negative price offers for resources may be needed to clear markets.
- The benefits of larger balancing areas with fewer transmission constraints are overwhelming. Resolving transmission constraints is critical because larger balancing areas lose much of the benefits associated with size if constraints are in play. Different parts of the country are exploring how to achieve the benefits of larger areas through direct balancing area consolidation or through efforts at “virtual consolidation” where separate balancing areas work together on particular issues. Smaller areas, such as island systems, will have special challenges that require additional control. Larger operating areas, with minimal transmission constraints and diverse variable generation assets, should be capable of dealing with the expected levels of variable generation.

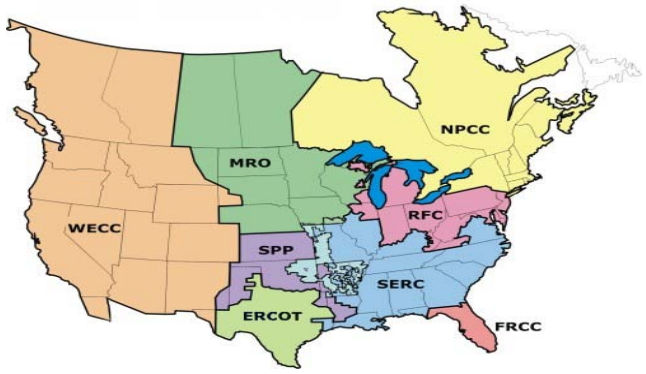
NERC's Mission

The North American Electric Reliability Corporation (NERC) is an international regulatory authority for reliability of the bulk power system in North America. NERC develops and enforces Reliability Standards; assesses adequacy annually via a ten-year forecast and winter and summer forecasts; monitors the bulk power system; and educates, trains, and certifies industry personnel. NERC is a self-regulatory organization, subject to oversight by the U.S. Federal Energy Regulatory Commission (FERC) and governmental authorities in Canada.[1]

NERC assesses and reports on the reliability and adequacy of the North American bulk power system divided into the eight Regional Areas as shown on the map below (See Table A).[2] The users, owners, and operators of the bulk power system within these areas account for virtually all the electricity supplied in the U.S., Canada, and a portion of Baja California Norte, México.



Note: *The highlighted area between SPP and SERC denotes overlapping Regional area boundaries: For example, some load serving entities participate in one Region and their associated transmission owner/operators in another.*

Table A: NERC Regional Entities

ERCOT Electric Reliability Council of Texas	**RFC** Reliability*First* Corporation
FRCC Florida Reliability Coordinating Council	**SERC** SERC Reliability Corporation
MRO Midwest Reliability Organization	**SPP** Southern Power Pool, Inc.
NPCC Northeast Power Coordinating Council, Inc.	**WECC** Western Electricity Coordinating Council

[1] As of June 18, 2007, the U.S. Federal Energy Regulatory Commission (FERC) granted NERC the legal authority to enforce Reliability Standards with all U.S. users, owners, and operators of the BPS, and made compliance with those standards mandatory and enforceable. In Canada, NERC presently has memorandums of understanding in place with provincial authorities in Ontario, New Brunswick, Nova Scotia, Québec and Saskatchewan, and with the Canadian National Energy Board. NERC standards are mandatory and enforceable in Ontario and New Brunswick as a matter of provincial law. NERC has an agreement with Manitoba Hydro, making reliability standards mandatory for that entity, and Manitoba has recently adopted legislation setting out a framework for standards to become mandatory for users, owners, and operators in the province. In addition, NERC has been designated as the "electric reliability organization" under Alberta's Transportation Regulation, and certain reliability standards have been approved in that jurisdiction; others are pending. NERC and NPCC have been recognized as standards setting bodies by the Régie de l'énergie of Québec, and Québec has the framework in place for reliability standards to become mandatory. Nova Scotia and British Columbia also have a framework in place for reliability standards to become mandatory and enforceable. NERC is working with the other governmental authorities in Canada to achieve equivalent recognition.

[2] Note ERCOT and SPP are tasked with performing reliability self-assessments as they are regional planning and operating organizations. SPP-RE (SPP – Regional Entity) and TRE (Texas Regional Entity) are functional entities to whom NERC delegates certain compliance monitoring and enforcement authorities.

Executive Summary

Existing state and federal energy policies including renewable portfolio standards (RPS) and production tax credits have driven development of wind plants in the U.S. and Canada that presently comprise in excess of 35 GW of installed capacity. This trend is projected to continue with the addition of many other forms of renewable technologies such as photovoltaics. Furthermore, other technologies like plug-in hybrid electric vehicles (PHEV), tidal-power systems, etc. are also on the horizon.

Unlike traditional, non-renewable resources, the output of wind, solar, ocean and some hydro generation resources varies according to the availability of the primary fuel (wind, sunlight and moving water) that cannot be reasonably stored. Therefore, these resources are considered variable, following the availability of their primary fuel source.

The North American Electric Reliability Corporation (NERC) is responsible for ensuring the reliability of the bulk power system in North America. Anticipating the growth of variable generation, in December 2007, the NERC Planning and Operating Committees created the Integration of Variable Generation Task Force (IVGTF), charging it with preparing a report [1] to identify the following:

1) Technical considerations for integrating variable resources into the bulk power system,

2) Specific actions, practices and requirements, including enhancements to existing or development of new reliability standards

One of the identified follow-up tasks from [1] was the need standard, valid, generic, non-confidential, and public power flow and stability models for variable generation technologies, and for a task force to review existing NERC Modeling, Data and Analysis (MOD) Standards to ensure high levels of variable generation can be simulated and appropriately addresses through the existing standards. This document constitutes the results of this review performed by this Task Force. A detailed discussion is provided of model and model validation in general, followed by an account of the current status of models for various variable generation technologies. Then a discussion is provided of the relevant NERC MOD standards and where they will need to be augmented to properly address variable generation.

Thorough out this report reference is made to various forms of models (standard, generic, user-written, 3-phase, etc.). It should be emphasized that the present and imminent need is to have models that are standard (i.e. a defined model structure used by all commercial software tools), publicly available and not specific to any particular design (i.e. “generic” and able to reasonably

represent key performance relevant to bulk power system studies) – this is the focus, which is further elaborate in the report. The process and need for model validation, however, applies to any and all levels of modeling.

An earlier draft of this report and recommendations were presented to NERC's Planning Committee at their March, 2010 meeting. The Committee members urged the IVGTF to pursue NERC reliability standard development. Thus, several NERC Standards Drafting Teams undertaking MOD Standard development will be contacted to present the recommendations from this report for their consideration and incorporation in subsequent updates.

1. Introduction

Existing state and federal energy policies including renewable portfolio standards (RPS) and production tax credits have driven development of wind plants in the U.S. and Canada that presently comprise in excess of 35 GW of installed capacity. This trend is projected to continue with the addition of many other forms of renewable technologies such as photovoltaics. Furthermore, other technologies, like plug-in hybrid electric vehicles (PHEV), are also on the horizon.

Unlike traditional, non-renewable resources, the output of wind, solar, ocean and some hydro generation resources varies according to the availability of the primary fuel (wind, sunlight and moving water) that cannot be reasonably stored. Therefore, these resources are considered variable, following the availability of their primary fuel source. There are two overarching attributes of variable generation that can impact the reliability of the bulk power system if not properly addressed:

1) Variability: The output of variable generation changes according to the availability of the primary fuel resulting in fluctuations in the plant output on all time scales.

2) Uncertainty: The magnitude and timing of variable generation output is less predictable than for conventional generation.

The North American Electric Reliability Corporation (NERC) is responsible for ensuring the reliability of the bulk power system in North America. Anticipating the growth of variable generation, in December 2007, the NERC Planning and Operating Committees created the Integration of Variable Generation Task Force (IVGTF), charging it with preparing a report [1] to identify the following:

3) Technical considerations for integrating variable resources into the bulk power system

4) Specific actions, practices and requirements, including enhancements to existing or development of new reliability standards

One of the identified follow-up tasks from [1] was the need for the models for variable generation technologies. For the purpose of completeness of this document, the proposed action item Task 1-1 from [1] is repeated below.

Item #	Proposed Improvement	Abstract	Lead	Deliverables	Milestones
1.1	Standard, valid, generic, non-confidential, and public power flow and stability models (variable generation) are needed and must be developed, enabling planners to maintain bulk power system reliability	Valid, generic, non-confidential, and public standard power flow and stability (positive-sequence) models for variable generation technologies are needed. Such models should be readily validated and publicly available to power utilities and all other industry stakeholders. Model parameters should be provided by variable generation manufacturers and a common model validation standard across all technologies should be adopted. The NERC Planning Committee should undertake a review of the appropriate Modeling, Data and Analysis (MOD) Standards to ensure high levels of variable generation can be simulated. Feedback to the group working on NERC Standards' Project 2007-09 will be provided.	*Ad Hoc* group: Members from IVGTF - Planning	Make recommendations and identify changes needed to NERC's MOD Standards	• Draft report ready by December 2009 PC meeting • Final report with recommendations to PC for endorsement in February 2010 • Develop SAR with Standards Committee if required.

Therefore, the goal of this document is to address the above action item and to provide:

1. The roadmap for development of valid, generic, non-confidential, and public standard power flow and stability (positive-sequence) models for variable generation technologies. Namely, what is available at present and what is the path forward to developing and deploying these models.

2. The NERC standards implications and feedback on what further NERC action items may be needed, if any, to address model application and validation as it relates to variable generation.

Throughout this report reference is made to various forms of models (standard, generic, user-written, 3-phase, etc.). The present and imminent requirement is to have models that are standard (i.e. a defined model structure used by all commercial software tools), publicly available and not specific to any particular design (i.e. "generic" and able to reasonably represent key performance relevant to bulk power system studies) – this is the focus, which is further elaborated upon this report. The process and need for model validation, however, applies to any and all levels of modeling.

2. The Need for Models for Variable Generation

The planning and operation of large interconnected power systems in diverse regions in the North American continent, is a complex task which requires daily analysis and computer model simulations. System planners and operators use simulation studies to assess the potential impact of credible (and sometimes extreme) contingency scenarios and to assess the ability of the power system to withstand such events while remaining stable and intact (i.e., to avoid cascading outages). When a credible disturbance event is simulated in computer models of the power system and the observed result is unacceptable performance, system planners and/or operators must develop either operating strategies or planned equipment additions (e.g., line re-conductoring, addition of shunt reactive compensation devices, etc.) to mitigate the potential problem. To help ensure proper assessment of reliable performance and to minimize (as much as possible) capital investment, models are required that reasonably represent actual equipment performance in simulations.

The NERC Modeling, Data, and Analysis (MOD) Reliability Standards require Registered Entities to create procedures needed to develop, maintain and report on models to analyze the steady-state and dynamic performance of the power system (MOD-011 and MOD-013). Equipment owners are required to provide steady-state and dynamic models (MOD-012) to the Regional Entities. This information is required to build a reasonable representation of the interconnected system for planning purposes, as stated in MOD-014 and MOD-015.[3] Specifically, models are required to perform powerflow, short circuit, and stability studies necessary to ensure bulk power system reliability.

Therefore, system models are required for generation equipment at three levels:

1. Models for assessing the steady-state behavior of the units and their fault current contributions for protection system analysis.
2. Models for emulating the dynamic behavior of the units for bulk power system time-domain stability analysis.
3. Detailed, equipment-specific (3-phase) models for specialized studies.

In this chapter, the aforementioned three categories of models are described in detail focused on variable generation technologies.

[3] http://www.nerc.com/page.php?cid=2|20

2.1. Steady-State and Fault Current Analysis

Steady-state analysis in the context of bulk power system studies is primarily associated with power flow, which determines the flow of power on transmission lines and transformers and the voltages at power system nodes (substations). Accurate calculations are essential in the planning and design of the interconnected power system to ensure that all equipment will be operated within its rated capability under various credible scenarios (including contingencies). These calculations are performed under various base-case conditions (i.e., all equipment generally in service) and contingency conditions that impact one or more power system elements such as a line, generating unit, or transformers out of service (e.g., for different system load conditions including peak load, light load, different seasons, or different power transfer).

To assess the adequacy of protection system settings, faults on transmission equipment are simulated and the settings for protection relays are evaluated, as well as the calculated fault currents are compared to the current rating of circuit-breakers.

Both these analyses are critical to the reliable operation of the power system. To perform these analyses, adequate models are needed for simulating the steady-state power flow and the fault current characteristics of generation equipment.

2.2. Time-Domain Positive Sequence Dynamic Models for Bulk Power System Stability Analysis

Time-domain simulations are a key tool for assessing the reliability of the bulk power system assessing the stability of the system.[4]

> "Reliability of a power system refers to the probability of its satisfactory operation over the long run. It denotes the ability to supply adequate electric service on a nearly continuous basis, with few interruptions over an extended time period.
>
> Stability of a power system refers to the continuance of intact operation following a disturbance. It depends on the operating condition and the nature of the physical disturbance."

Similarly, NERC defines stability as, "The ability of an electric system to maintain a state of equilibrium during normal and abnormal conditions or disturbances."[5]

[4] The definitions listed are quoted from: P. Kundur, J. Paserba, V. Ajjarapu, G. Andersson, A. Bose, C. Canizares, N. Hatziargyriou, D. Hill, A. Stankovic, C. Taylor, T. Van Cutsem and V. Vittal, "Definition and classification of power system stability: IEEE/CIGRE joint task force on stability terms and definitions", IEEE Transactions on Power Systems, Volume 19, Issue 3, Aug. 2004, pp: 1387 – 1401. (http://ieeexplore.ieee.org)

Stability analysis is traditionally performed using positive-sequence models. This includes models that focus on system simulation under assumed perfect balanced conditions (i.e., no imbalance in the 3-phase system voltages and currents). Furthermore, the primary stability issues that are investigated (angular stability, voltage stability, frequency control/stability) for bulk power systems tend to be bounded within a small frequency band around the system fundamental frequency. Positive sequence models are typically required to be valid in a range of roughly 0.1 Hz to about 3 Hz, with the control system having validity up to 10 to 15 Hz to allow for investigating general control loop stability. With these simplifying assumptions, it has been historically easy to establish generic, non-proprietary models for representing conventional generation and its controls. Functional models that are non-proprietary and generic (i.e., applicable to any vendors equipment, simply by changing the model parameters) are needed for the various variable generation technology. A library of models to deal with each family of variable generation technology is required to support reliability assessment. What is presently available, and what must be further developed is discussed in the next chapter.

Aside: *There are many cases were extended term analysis may be necessary, in which case wind speed variations may be a needed input to the model. For the purposes of typical stability analyses, however, where the study period spans over only several seconds, wind speed is typically assumed to be constant.*

2.3. Detailed Three-phase Equipment Level Models

There are a number of potential interaction issues that may occasionally require detailed analysis [2]. To perform this analysis, detailed three-phase equipment models are required.

Subsynchronous resonance (SSR) is a phenomenon whereby series compensation of a transmission line results in electrical resonance frequencies in the subsynchronous frequency range that can lead to destabilizing modes of mechanical torsional vibration on the turbine-generator shaft that fall in the frequency range of the electrical resonance.[6] These resonance phenomena are only of concern to generation technologies with a mechanical turbine-generator shaft that is coupled to the electrical system. Type 1, 2 and 3 Wind-Turbine Generation (WTG) may be susceptible.[7] Clearly, Type 4 (where the unit is decoupled from the electrical system) and technologies like PV have no such concerns. SSR is less likely to affect wind turbines compared

[7] See Appendix I for more information on these WTG configurations.

to large conventional synchronous generators since the typical torsional mode for a wind turbine is quite low (around 1 to 4 Hz). Accordingly, it would be quite unlikely that the level of series compensation in a system would be high enough to result in an electrical resonance that would interact with a low mechanical frequency.[8] A larger concern is induction machine self-excitation.[9] Some detailed 3-phase analysis and discussions with the wind turbine manufacturer on a case by case basis is prudent when installing wind near series compensated lines.

Another potential phenomenon related to torsional mechanical modes is device dependant subsynchronous oscillations, often referred to in the literature as subsynchronous torsional interaction (SSTI). This was first observed at the Square Butte HVDC project in 1976.[10] SSTI is a phenomenon by which controls associated with power electronic based transmission equipment (e.g., SVC or HVDC) may introduce negative damping torques in the frequency range associated with the torsional mechanical modes of oscillation of nearby thermal turbine-generating units. Again, due to the relatively low frequency range for torsional modes of wind turbine, this may not be a concern in most cases; however, where wind plants are closely coupled to a HVDC system, analysis is prudent to ensure that control and/or torsional interaction do not occur. This analysis will typically require detailed three-phase models for both the wind plant and the HVDC system. Also, SSTI is not necessarily detrimental[11] because, in some cases, torsional damping can be markedly improved through the application of power electronic devices. One thermal power plant in the Western U.S. grid uses a dedicated SVC for this purpose as a means of mitigating the effects of SSR. [12] A practical example of this is the Taiban Mesa wind plant located in New Mexico. This wind plant is located electrically adjacent to a back-to-back HVDC station – Blackwater. The detailed interconnection studies performed by ABB during the design of the wind plant showed that there was little risk of torsional interaction between the HVDC controls and the wind turbine generators. This analysis required detailed equipment level (3-phase) models of the wind turbines, the HVDC and transmission network.

[8] Note: The electrical resonance needs to be in the range of 56 to 59 Hz on a 60 Hz system found in North America.

Other phenomena that may expose the shaft of a WTG to cyclical and significant transient torque pulsations may also be a concern. For example, nearby arc furnaces, or high-speed re-closing on a transmission line emanating from the wind plant substation, or repeated commutation failures on a nearby conventional line-commutated HVDC. As a first step, some simple transient stability analysis may be performed to estimate the expected step change in the electrical torque on a wind turbine generator due to the electrical event, and the wind turbine manufacturer consulted to identify if the observed level of transient torque is a concern. Based on consultation with the wind turbine manufacturer, more detailed analysis may be required to assess if a potential problem exists and how it may be remedied.

Another issue that may be of concern is the stability and behavior of variable generators in extremely weak short-circuit nodes of the power system and regions of the system that may be highly susceptible to islanding. Again, more detailed models than positive sequence stability representations may be needed to study these scenarios (e.g., to accurately review the potential for temporary over voltages upon islanding, etc.). Also, in some cases and designs (e.g., Type 3 WTG), the behavior of the unit as it pertains to voltage-ride through during fault scenarios can be more onerous on the controls (i.e., controlling the DC bus voltage in the Type 3 WTG) for unbalanced fault scenarios as opposed to a balance 3-phase faults. Thus, 3-phase detailed equipment models are needed to assess these phenomena.

Finally, transient stability studies should be completed to ensure that basic control loops in the variable generation plants (e.g., central voltage control systems often deployed in doubly-fed and full-converter based wind plants that regulate voltage at the interconnecting substation by adjusting the reactive output of all wind turbines in the wind plant) do not interact or interfere with other nearby transmission and generation controls. This often requires proper tuning of the controls.

This brief section illustrates the need for the availability of detailed 3-phase equipment level models, which cannot be generic. These models are likely to be proprietary and may need to be used under non-disclosure agreements between the vendor and the plant developer/utility. Therefore, it is important to recognize the need for these models so that they are developed and available to be easily deployed and used when such specialized studies are needed.

2.4. Summary

This chapter has outlined the basic power generation plants models required power system analysis related to reliability assessment. In addition, these models need to be generic (i.e., the model structure applicable to any vendor's equipment, with only the variation of the model parameters to represent various vendor equipment) and non-proprietary (i.e., publicly available to all stakeholders). Adequate models readily exist for conventional synchronous generators, but, until recently, have been unavailable for any variable generation technology. In the next chapter the current status of models for all variable generation technologies is discussed.

3. Present Status of Modeling Variable Generation

This chapter provides an overview of the models and modeling capability presently available. In the summary of this chapter the gaps are identified and areas requiring further work are identified. The modeling and model development discussed here is primarily for power system power flow, short-circuit and stability analysis.

Time-domain stability analysis is concerned with phenomena in the tens of milliseconds to several minutes time frame (see Figure 3.1).

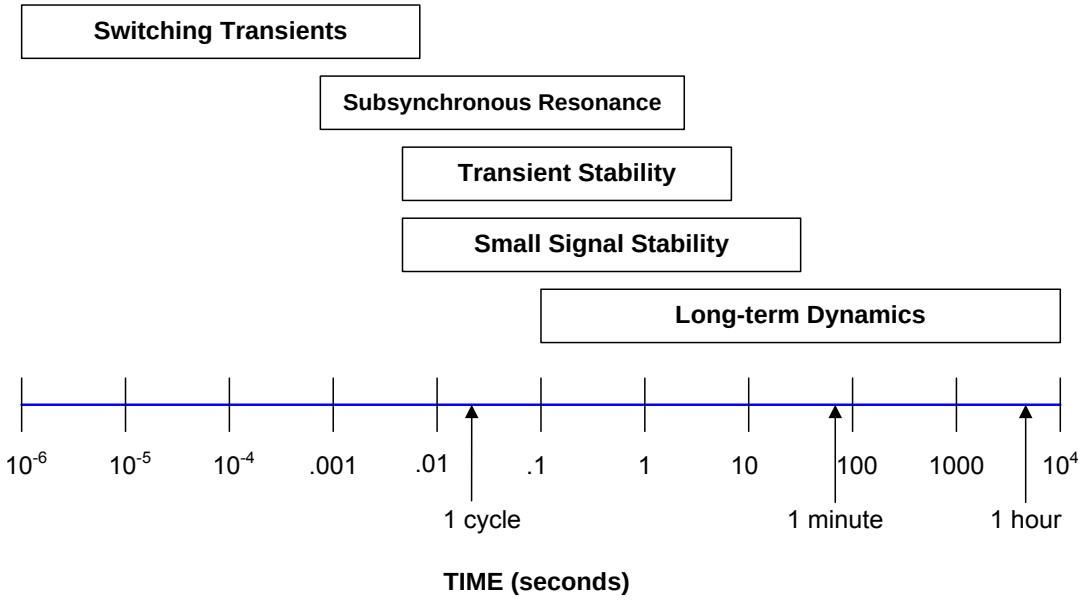

Figure 3.1: Times of various phenomena of interest in power system studies (GE).

3.1. Wind Generation

3.1.1 WECC/IEEE Effort for Generic Models

The size of individual WTGs has increased dramatically from several hundred kilowatts to multi-megawatt turbines. The size of individual wind power plants has also increased significantly. In the past, a typical wind power plant consisted of several turbines. Presently, wind power plants

of several 100 MW and larger are being proposed. By some projections,[13] as much as 300 GW (20% penetration) of wind generation capacity is forecast in the U.S. by 2030 and NERC projects an increase of 229 GW of new wind generation installed capacity by 2018.[14] The increased penetration of renewable energy generation poses significant questions concerning the ability of the power system to maintain reliable operation.

Presently, most wind turbine technologies use power electronics and advanced reactive power compensation as an integral part of wind turbine generator and wind power plant. Under dynamic transients, the behavior of modern wind turbines must be accurately simulated to predict the response of the wind power plant. Misrepresentation of WTGs in transmission studies may threaten the reliability of power systems by either resulting in excessive overbuild of transmission systems due to pessimistic models, or in deficient transmission system investment based on optimistic models.

Turbine manufacturers have developed dynamic models for their wind turbines. These dynamic models are typically user-written models in commercially available power system simulation software platforms (e.g., Siemens PTI PSS™E, GE PSLF™, DigSILENT PowerFactory, etc.). Detailed three-phase equipment level models of WTGs used for internal design purposes are also often developed by manufacturers in either their own simulation platforms or commercial software tools including PSCAD® or Matlab® Simulink.

Unfortunately, both these categories of models (the user-written positive-sequence models and the three-phase detailed equipment models) require significant input data/parameters considered to be proprietary by the turbine manufacturers and therefore are not freely available to the general public. Access to these models usually requires a non-disclosure agreement (NDA) between the dynamic model user and the turbine manufacturers. This agreement is only valid for a specific turbine model, for a given period of time.

In many cases, it takes months to negotiate and to finalize the NDA. Furthermore, in some cases there are incompatibilities among turbine models developed by different turbine manufacturers which results in numerical interactions if multiple user-written models are incorporated into a single power system model for system analysis. This makes the work of power system planners almost impossible. The NDA are also usually bilateral, which renders it impossible to share the information among the manufacturers to help resolve incompatibility problems. Finally, the NDAs make it difficult, at best, and impossible, in some cases, to share the models thereby potentially violating the NERC requirements for submitting models for system planning studies.

[13] http://www.nrel.gov/docs/fy07osti/40482.pdf
[14] http://www.nerc.com/files/2009_LTRA.pdf

With this back drop, the WECC Wind Generator Modeling Group (WGMG) initiated the development of generic wind turbine models of the four (4) different types of wind turbines (see Appendix I for these four WTG designs). These four types of turbines currently hold the largest market share throughout the world. WECC is interested in providing accurate and validated models of standard wind turbines that will be available in their database, including the datasets to be used for testing the models, and the methods for representing a wind power plant in power system studies. These goals are being accomplished through the development and validation of standard models. The standard models must be generic in nature – that is, they must not require nor reveal proprietary data from the turbine manufacturers. These improved standard (generic, non-proprietary) dynamic models enable planners, operators and engineers to perform the necessary transmission planning studies required to ensure system reliability.

Currently, the first generation of these generic WTG models, for all four turbines types, have been developed and are available as part of the main model library for the two most widely used commercial power system simulation tools in North America (i.e., Siemens PTI PSS™E, GE PSLF™)[15]. As a continuation of, and in parallel with, the WECC effort, the Institute of Electronic and Electrical Engineers (IEEE), Power & Energy Society (PES) has also established a Working Group to investigate WTG modeling issues: The IEEE Working Group on Dynamic Performance of Wind Power Generation, under the Power System Dynamic Performance Committee. This Working Group is actively expanding the efforts of generic dynamic modeling for wind power plants, focusing on modeling specifications, disseminating methods and model validation.

To date, the first generation of generic models developed and released have focused on capturing the response of the units to electrical voltage disturbances on the transmission grid (grid faults). One deficiency, particularly for the Type 1 and 2 models, is the proper representation of unit responses to large system frequency excursions. These models have not been verified due to the lack of data on actual turbine behavior under such circumstances and will require further development, in consultation with turbine manufacturers.

Finally, as with all modeling exercises, model development and validation are iterative processes, requiring:

- Generic wind turbine models are to be made available to the public.

[15] PSS®E-32.0 Program Application Guide: Volume II, Chapter 21.
PSS®E-32.0 Model Library, Chapters 17 through 21
GE PSLF User's Manual. v.17.0_04. October, 2009.

- Generic wind turbine models must be validated before release and public dissemination, which is being pursued in WECC, IEEE, International Electrotechnical Commission (IEC) and other forums.
- Models should evolve and be revalidated as the technology progresses.
- Data from field measurement and monitoring for model validation can be a vital resource.

A somewhat unique need in modeling variable generation (e.g., wind) is the need for methods required to develop equivalent models for large wind power plant. In contrast to conventional fossil fuel and hydro power plants, where plants are constituted by either a single large unit or, at most, a few large units, a wind power plant can be made up of tens to more than a hundred WTGs. For large scale power system simulations, particularly in North America where the power system models are quite large, it is often preferred to reduce the wind power plant to a single equivalent unit. Accordingly, techniques are needed for model aggregation and testing their validity – some significant progress has been made in this regard. For example, Figure 3.2 shows the technique developed for reducing the impedance of the wind power plant collector system into a single, equivalent feeder impedance for representation of the wind power plant (WPP) by an aggregated single equivalent unit in power system studies.

Figure 3.2: Example shows the method for reducing the impedance of a wind power plant collector system into a single equivalent impendence.[16]

[16] "WECC Wind Generator Power Flow Modeling Guide" (http://www.wecc.biz/library/WECC%20Documents/Documents%20for%20Generators/Generator%20Testing%20Program/Wind%20Generator%20Power%20Flow%20Modeling%20Guide.pdf)

Figure 3.3 shows an example for dynamic simulations of aggregating the WPP into a single equivalent unit and an equivalent single impedance representing the entire collector system as compared to a detailed model representing the whole WPP unit-by-unit – the example shown assumes that all WTGs in the WPP are identical, in cases where this is not true multiple equivalent units may be needed one for each WTG type. As can be seen in this figure, the results from the two simulations compare very well at the point of interconnection (which is what is shown); thus, the equivalent aggregate is adequate for power system studies.[17]

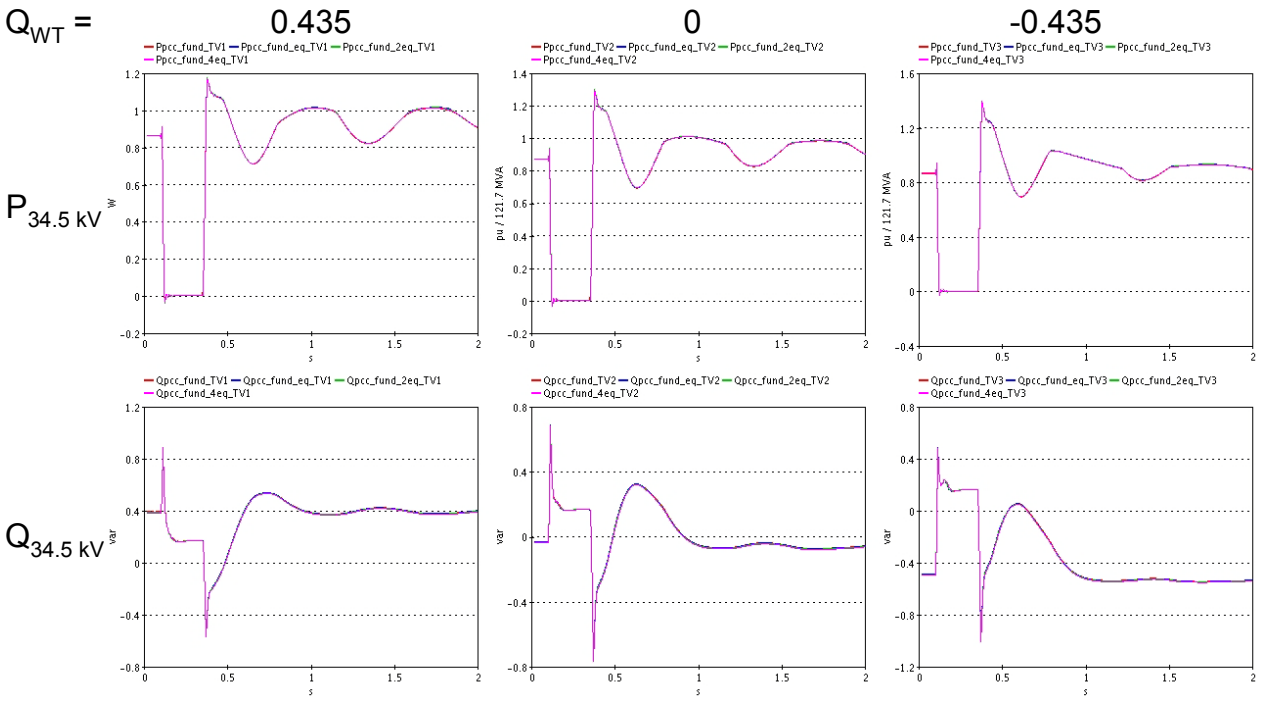

Figure 3.3: Example of time-domain simulations comparing a detailed model of a Wind Power Plant (i.e., representing the complete collector system and each WTG individually), versus a single-machine equivalent aggregate (i.e. the entire plant is represented by one equivalent unit and an equivalent impedance to represent the whole collector system).

[17] Figure is from J. Brochu, R. Gagnon and C. Larose, "Validation of the WECC Single-Machine Equivalent Power Plant", Presented at the IEEE PES DPWPG-WG Meeting at IEEE PSCE, March 2009.

3.1.2 UWIG Generic Model Documentation and Validation Effort

The Utility Wind Integration Group (UWIG),[18] under a U.S. Department of Energy grant, will be launching an effort to provide the basic documentation, application, and validation of generic models for wind turbines. The goal of this project is to accelerate the appropriate use of generic wind turbine models for transmission network analysis.

The objectives of the project, which will commence in early 2010 and run for a period of two years, are to:

- Complete characterization and documentation of the four generic models developed through an outgrowth of a WECC activity begun in 2005;
- Defining proposed enhancements to the generic wind turbine model structures that would allow representation of more advanced features including power control, automatic curtailment, inertial and governor response;
- Comparative testing of the generic models against more detailed (and sometimes proprietary) versions developed by turbine vendors;
- Developing recommended parameters for the generic models to best mimic the performance of specific commercial wind turbines;
- Documenting results of the comparative simulations in an application guide for users;
- Acquiring test data from all available sources for the purpose of validating the performance of the appropriately specified generic models in actual case studies;
- Conducting technology transfer activities in regional workshops for dissemination of knowledge and information gained, and to engage electric power and wind industry personnel in the project while underway.

[18] The UWIG was established in 1989 to provide a forum for the critical analysis of wind technology for utility applications and to serve as a source of credible information on the status of wind technology and deployment. The group's mission is to accelerate the development and application of good engineering and operational practices supporting the appropriate integration of wind power into the electric system. It currently has more than 150 members spanning the United States, Canada, and around the world including investor-owned, public power, and rural electric cooperative utilities; transmission system operators; and associate member corporate, government, and academic organizations http://www.uwig.org/aboutuwig.htm

Maintaining communication and coordination with other ongoing activities and agencies engaged in this topic is another objective of the effort which will be critical for success.

3.1.3 IEC Effort for Generic Models

The International Electrotechnical Commission (IEC) recently started a Working Group in October 2009 to address the development of generic and "standard" models for wind turbine generators.[19] The goal of this Working Group is to define standard dynamic simulation models for wind turbines and wind plants, which are intended for use in power system and grid stability analyses, and should be applicable for dynamic simulations of power system events including short circuits (low voltage ride through), loss of generation or loads, and system separation. The group is approaching this work in two parts. Part 1 will focus on specifying dynamic simulation models for the generic wind turbine topologies/concepts/configurations presently in the market, as well as specifying how these models may be modified as future technologies/concepts are introduced. The standard should also include procedures for validation of the models specified. Another goal is that the models should be developed and specified at a fundamental level so they are independent of any specific software platform and can be adopted by any software vendor.

Part 2 of this work will be focused on extending the modeling to allow for modeling of the entire wind power plant, including wind power plant control and auxiliary equipment.

Several members of this IEC Working Group are also members of the WECC and IEEE Working Groups (and this NERC Task Force). The three groups are clearly working in close collaboration to ensure maximum benefit to the industry globally and maximum sharing of knowledge already gained through the WECC and IEEE efforts.

3.2. Photovoltaic Solar Generation

Photovoltaic (PV) systems for power generation are quickly increasing becoming a significant portion of generation in some regions in North America. PV or solar arrays are composed of a large number of solar cells connected in series and parallel. These cells produce a DC voltage when they are exposed to sunlight due to the photo-voltaic effect[20]. Figure 3.4 shows the I-V characteristics of a cell at a constant temperature and various sun intensity or *insolation* levels.

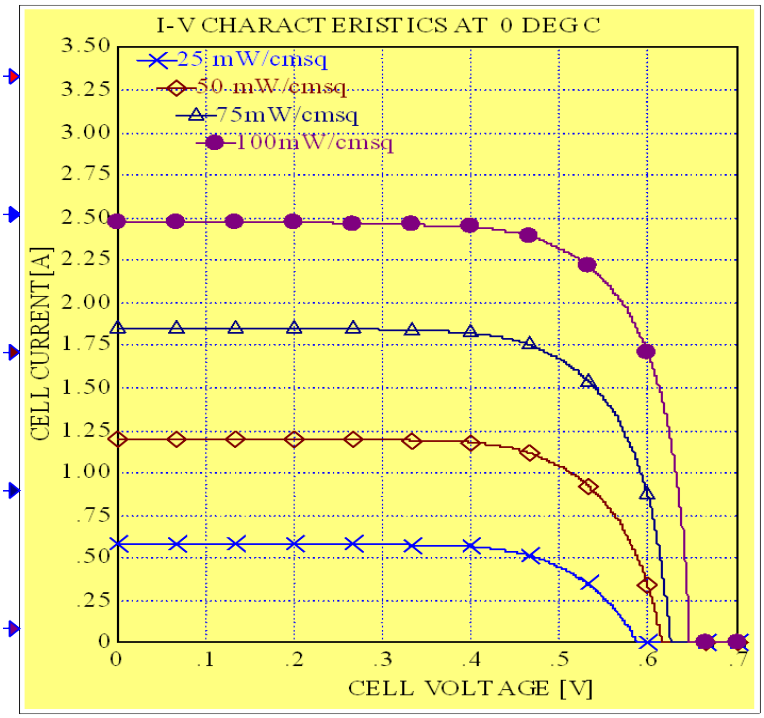

Figure 3.4: Current-Voltage characteristics of a solar cell for various insolation levels at a constant temperature (source [11][21]).

[20] The photo-voltaic effect is the process by which an electric potential difference (voltage) is created in a material exposed to light (electromagnetic radiation), which then leads to the flow of electric current. This process is directly related to the photo-electric effect, but distinct from it in that in the case of the photo-electric effect electrons are ejected from the material surface upon being exposed to high enough frequency (energy) light, whereas in the photo-voltaic effect the generated electrons are transferred across a material junction (e.g., PN junction in a photo-diode) resulting in the buildup of a voltage between two electrodes and the flow of direct current electricity.

[21] Solar Radiation Research Laboratory at the National Renewable Energy Laboratory (http://www.nrel.gov/midc/srrl_rsp/)

Figure 3.5 shows that the current is limited when the cell is short-circuited (Voltage=0).

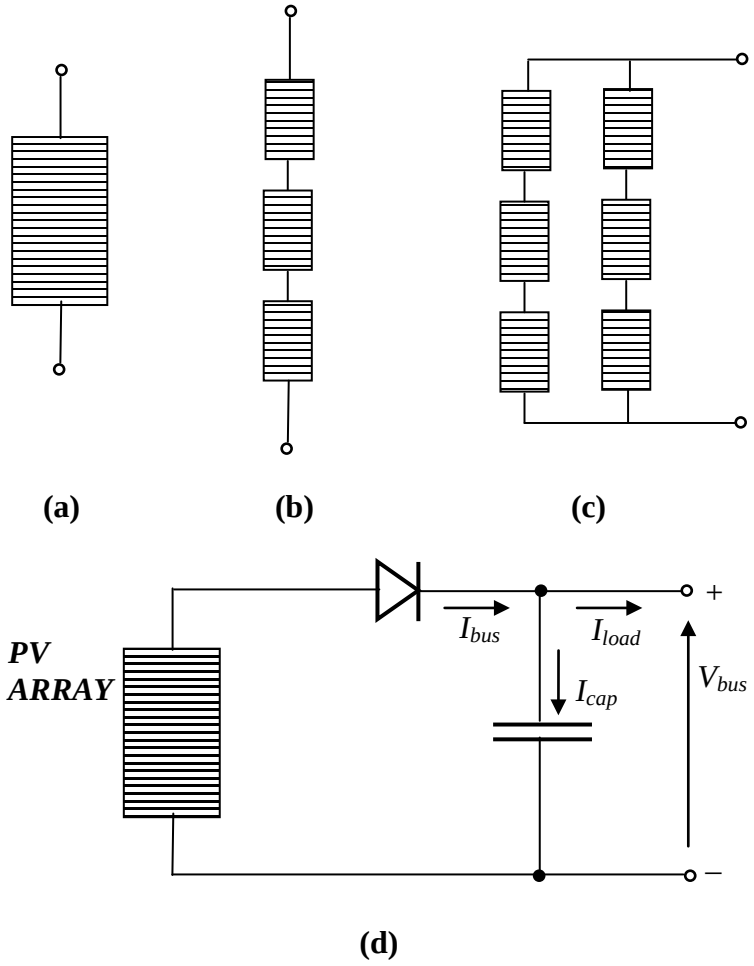

Figure 3.5: The concept of a solar array: (a) a single solar cell, (b) a series connection of solar cells (N_{ser} = 3 and N_{par} = 1), and (c) a solar array (N_{ser} = 3 and N_{par} = 2). The solar cell array(s) is then connected to a DC bus (d).

Figure 3.5 shows the concept of the solar cell up to the solar array. To use the DC power generated by the PV array in an AC power system, the DC power must be converted to 60 Hz AC in North America (50 Hz in some other regions in the world, like Europe). There are several power electronic based converter concepts that can achieve this, which can be classified into two general categories: line-commutated converters (LCC) and self-commutated or more commonly

referred to as voltage-source converters (VSC). These technologies have been applied for decades and are well understood. LCC use thyristors as their controlled switching device. The switching on of a thyristors can be controlled, while the turn-off time cannot be controlled and happens at the next AC waveform current zero crossing. LCC systems must be operated in a network with an AC source and cannot operate to serve an isolated load. In contrast, VSC systems are self-commutating, that is the power electronic switching devices used (e.g., integrated gate-commutated thyristors or IGCTs and insulated-gate bipolar transistors or IGBTs) are able to be completely controlled for both turn-on and turn-off and allow the VSC to completely control the AC waveform produced and adjust the power factor as seen on the AC side to within the current rating of the device. Due to advances in the technology, most power electronic converters employed in PV systems are of the VSC type.[22]

From a modeling standpoint for power system studies, there are some user-written manufacturer-specific models in existence as developed by various PV manufacturers. Presently, no generic or standard models exist.

The WECC Working Group, which has been addressing the development of generic WTG models, will be extending its effort in 2010 to review developing generic PV models for dynamic simulations in stability studies. As a starting point, the grid side structure of the Type 4 WTG model may be used since it represents a VSC. This is because PV is typically connected to the grid with a VSC and it will behave electrically similar to a Type 4 WTG that has a similar electrical interface with the grid—this is from a grid perspective looking at the electric response and neglects any of the effects of the energy source.

From a steady-state, power flow and short-circuit analysis perspective, the behavior of the PV technologies will behave in a similar fashion to a Type 4 WTG because of the VSC interface, and because its power factor can be controlled based on the control functionality of the VSC design. Its short-circuit response will be limited to the current limit effected by the VSC under grid fault conditions.

The development of generic and standard PV models is presently a topic for further research. This should be pursued imminently and much of what has been learnt from the WTG model development process should be leveraged.

[22] IEA-PVPS: Grid-Connected Photovoltaic Power Systems: Survey of Inverter and related Protection Equipment; Report IEA PVPS T5-05: 2002, December 2002 (http://www.iea-pvps.org/products/download/rep5_05.pdf).

3.3. Solar Thermal

Solar thermal energy is based on harnessing the radiated heat of the sun for the purpose of producing electricity. In broad terms, there are presently two main ways of achieving this:

1. Concentrating Solar Power (CSP) plants – in this case solar radiation is typically collected through a large number of mirrors (thus a large amount of solar radiation) which is then focused on a small area – the mirrors have tracking systems to follow the Sun. The concentrated solar radiation heats a high temperature working fluid, which then feeds a conventional steam-turbine generator. From an electrical grid perspective, the models needed to simulate the steady-state, short-circuit and transient time-domain dynamics of such a generating unit, are typically no different than standard synchronous generating units for fossil fuel plants.

2. The Stirling Engine concept[23] – in this design a parabolic mirror assembly concentrates the collected solar radiation on a sterling engine that sits at the focal point of the mirror assembly. A Stirling engine is a reciprocating heat engine that operates based on the concept of cyclical compression and expansion of a working fluid. As the working fluid expands/contracts it drives a piston that then turns a generator. The engine is connected to an electrical generator that produces electric energy. Once again for power system studies the units may be modeled using standard generator models. However, in this case a power plant would be constituted by a large number of small units (the typical Stirling engine is about 25 kW) in a large electrical collector system that collects the power and injects it into the utility grid – much like the collector system of a wind power plant. Thus, modeling the collector system (e.g. see Figure 3.2 for an aggregate model of a wind collector system) and any other devices in the collector system, such as shunt reactive devices etc. must be properly modeled

3.4. Tidal Generation

Tidal power generation derives energy directly from the motion of oceanic tides. The gravitational pull of the Moon and Sun, combined with the Earth's rotation result in the generation of tides. Tides generally occur with a period of roughly twelve hours, and so most coastal areas experience two high and two low tides within every twenty-four hour period. Tidal generation uses this phenomenon to generate energy. Clearly, the stronger the tides are, either in tidal current velocity or the height/level of water, the greater the potential amount of energy generation.

[23] http://www.stirlingenergy.com/ Y. Zhang and B. Osborn, "Solar Dish-Stirling Power Plants and Related Grid Interconnection Issues", *IEEE PES General Meeting*, 24-28 June 2007.

Presently, in North America tidal power is not a significant source of power in any region. Some pilot programs exist for introducing the technology. In April 2009, one was announced in Snohomish County Public Utility District in Washington State.[24]

There are several options for harnessing tidal power. One method is the use of turbines similar to wind turbines; however the fluid (water) is much denser and requires a turbine with smaller and bulkier blades, as shown in Figure 3.6. Most of these technologies typically use AC/DC/AC converter technology, similar to a Type 4 wind turbine, to convert the low frequency generated electricity to grid frequency AC electricity and interface with the power system. Once this technology becomes more prevalent a starting point for development of a suitable model structure may be the Type 4 generic wind turbine models. Understandably, the energy source characteristics are quite different from wind power and significantly more predictable.

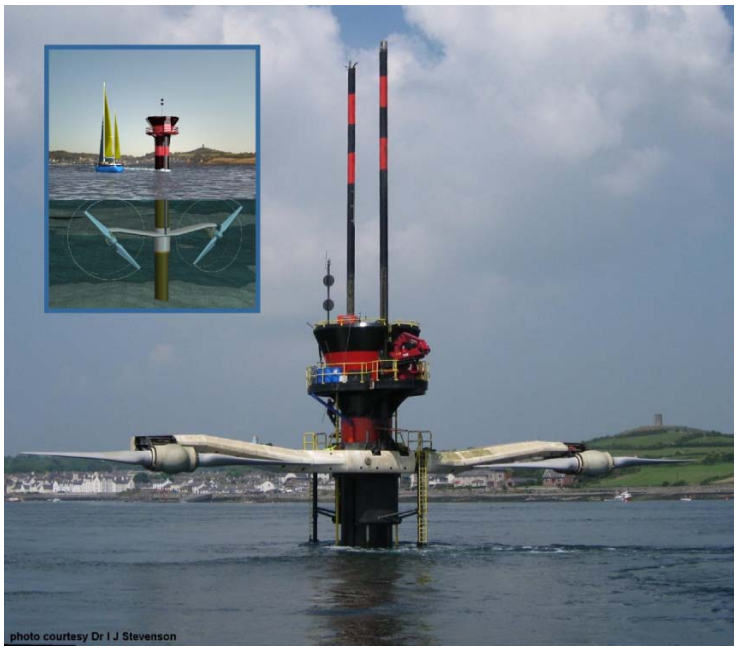

Figure 3.6: One of the many concepts for tidal generation systems (courtesy of Marine Current Turbines Limited, www.marineturbines.com).

3.5. Other Resources

There are several other emerging technologies and there are many complementary technologies (i.e., auxiliary to the variable generation resources, but designed to help with their integration into the grid) including smoothly-controlled dynamic reactive devices (static VAr systems),

[24] http://www.snopud.com/PowerSupply/tidal/tidalpress.ashx?p=1516&756_na=46

energy storage technologies etc. With respect to static VAr systems (SVCs and STATCOMs), there is an active WECC working group imminently addressing the issue of generic models for these devices.[25] The group has made substantial progress with the models defined and developed, but currently undergoing testing and validation. With regards to the other emerging technologies, most tend to be power converter based (i.e., connected to the grid through a back-to-back frequency converter) and so their electrical behavior (neglecting the characteristics of the energy source) will be similar to Type 4 wind turbines. Until these technologies mature, the basic structure of other more mature converter based generation technologies can be a good starting point.

3.6. Summary

This section has briefly presented the various types of variable generation and the present status of models and model development for power system studies. Wind generation technologies, being the most prevalent world-wide, have the most mature models. Through efforts started by WECC and being continued by IEEE and IEC, generic standard models for the four main types of WTG technologies are being developed. The first generation of these models has been released in two power system simulation software platforms most commonly used in North America. Other emerging technologies (e.g., PV, tidal power, etc.) can build on this effort to start developing generic models. For example, the WECC effort will be extending its scope in 2010 to look at PV model.

From a NERC perspective the key items are:

1. To emphasize and support efforts by WECC, IEEE and IEC to develop and standardize generic models for these technologies for power system planning studies.
2. To encourage manufacturers to familiarize themselves with the generic models being developed and be willing an able to supply parameters for these generic models to reasonably represent their equipment for power system stability studies. As highlighted in Chapter 2, more detailed manufacturer specific models may be needed in special cases and for specialized studies.
3. To encourage efforts aimed at model validation.
4. To consider any augmentation or additions to reliability standards related to Modeling, Data and Analysis (MOD) with respect to modeling and model validation of variable generation. This is discussed in greater detail in section 5 of this report.

[25] http://www.wecc.biz/committees/StandingCommittees/PCC/TSS/MVWG/SVCTF/default.aspx

4. Present Status of Model Validation

This chapter gives an overview of the model validation work that has been done hitherto as it relates to models for variable generation. Necessarily, the primary focus of this section is on wind turbine generator models, since models for this resource are presently the most mature.

4.1. What is Model Validation?

Any and all models of a dynamic system always have limitations associated with them. A model is a representation of reality; it is an emulation – that is why it is called a model. In developing a model first the question is asked as to the specified use of the model and the conditions it must reasonably emulate – this forms the basis of a model specification from which a model is developed. The developed model establishes a certain structure with parameters, which are adjustable in order to emulate different types of equipment or design of the modeled device. Thus, valid parameterization of the model to represent a particular manufacturer's equipment is essential to support the particular scenarios to be analyzed.

Model validation is often achieved through some form of testing, either in a laboratory/factory or in field. There is a range of reasons for conducting tests for wind generation. Each test has a unique set of objectives guiding the design of adequate testing practices.

- Performance Compliance: Compliance to contractual requirements and grid codes are one reason to perform tests. Interconnection requirements (usually included in plant Power Purchase Agreements and Interconnection Contracts) and grid codes typically outline specific technical criteria that must be met to allow a power plant to connect and operate on the grid. Since these criteria point out specific levels to be met, (for example, voltage, power factor, and response time) tests may be designed with binary "pass/fail" objectives.

- Model Validation: In much of the world, power plants above a pre-defined size must be accurately represented with a dynamic simulation model used in stability analysis for operations and planning purposes. As variable generation sources such as WPP are growing in size, it is becoming increasingly important to have accurate variable generation specific models. Tests may be performed to tune and verify simulation models to closely match the performance of actual equipment. In the western U.S. and Canada, WECC has mandated that any plant with 20 MVA aggregate generation must be tested for model validation, including large wind power plants. For North America, the imminent NERC MOD-026 standard presently under development will enforce model validation requirements throughout the North American region.

To achieve the goals of model validation, there are three categories of tests that may be performed:

- Type Tests: These are tests performed by the manufacturer or independent third-parties of representative equipment. The intent is to demonstrate that a particular design of equipment exhibits specific performance, and all other equipment of that same design is assumed to have the same performance. Type tests can be:
    - *Component:* Performed on specific functions or features in a power plant or generation equipment. This could be, for example, testing the fault ride-through capability or reactive capability of a WTG, where testing is performed at the component level.
    - *Factory:* A systemic test of a major assembly (i.e., a drive train) or entire turbine-generator is performed under a controlled environment like a manufacturing facility to verify performance and validate assembly design.
    - *Unit:* A systemic test of multiple components operating together (i.e., as entire operating WTG or WPP) with the specific intent of benchmarking a model or design as a type test. For example, tests performed in Europe under the WindTest program.
- Field Tests[26]: Tests performed by the power plant asset owner, developer, host utility, manufacturer and/or independent third-parties of specific operating equipment. These tests are to demonstrate that a particular implementation, design and installation of equipment exhibit specific performance.
    - *Commissioning:* Tests performed on new equipment entering its period of commercial operation service.
    - *Periodic Maintenance or Calibration:* Tests performed periodically after the plant is in commercial operation to verify that equipment continues to perform as well as it did during commissioning.

[26] See for example: WSCC Control Work Group and Modeling & Validation Work Group, "Test Guidelines for Synchronous Unit Dynamic Testing and Model Validation", February 1997. (www.wecc.biz), and IEEE Task Force on Generator Model Validation Testing, "Guidelines for Generator Stability Model Validation Testing", Proceedings of the IEEE PES General Meeting, Tampa, FL, June 2007 (http://ieeexplore.ieee.org)

- *Periodic Model Validation:* Tests performed periodically after the plant is in commercial operation to verify that simulation models adequately represent actual plant performance (for example, the periodic model validation testing required by WECC).
- *Periodic Codes & Standards Validation:* Tests performed periodically after the plant is in commercial operation to benchmark and validate plant performance per contractual requirements. These tests are typically performed to obtain a permanent operating license for the power plant.

- On-Line Monitoring[27]: Other information of interest is from continuous data gathering based on ongoing performance of an operating power plant. Data collected from external and unscheduled events, including grid disturbances or in the case of WTG large changes in wind is particularly useful. Monitoring also benchmarks performance under normal operation.

With these general concepts in mind, the following subsections present some example cases studies of model validation and validation approaches for variable generation sources. The examples emphasize WPP and WTG, since wind generation is the present dominant variable generator sources in the North America continent.

4.2. Examples of Model Validation Efforts

4.2.1 Hydro- Québec Example

The province of Québec has vast wind energy potential. Though wind energy generation in 2009 accounts for nearly 1.3% of the total installed capacity in the Québec control area, the penetration rate of wind energy generation will reach 10% by 2015. A total capacity of 528 MW is currently in operation and approximately 3,000 MW are under development. Five wind turbine manufacturers will supply the WTGs for the different projects under study.

The configuration of the Hydro-Québec transmission system is essentially radial. Approximately 85% of the total installed generation feeding the system is located at distances up to 1,300 km

[27] See for example: P. Pourbeik, "Automated Parameter Derivation for Power Plant Models From System Disturbance Data", Proceedings of the IEEE PES General Meeting, Calgary, Canada, July 2009 (http://ieeexplore.ieee.org). This reference shows actual application of on-line disturbance monitoring to power plant model validation for conventional fossil fuel generation. It may be feasible to apply similar algorithms and approaches for continuous re-validation of WTG and other variable generation technologies once generic standard models have been developed. This is a current topic for research.

from the closest major load centers. With this configuration, the system transfer capability is mainly limited by stability constraints (transient stability and voltage stability) rather than congestion or thermal capacity of equipment; hence the need for reliable models for wind power plants and all other generation.

Stability studies are critical to determine the compensation equipment required to maintain the reliability of the power system when integrating new generation. They are also essential for operation planning studies including control system design and tuning and determination of transfer capabilities.

So far, Hydro-Québec has faced two major difficulties regarding user-written models provided by the wind turbine manufacturers. First, models often lack robustness and do not represent accurately some important features (convergence problems in low short-circuit network, do not take into account frequency excursions, do not represent secondary voltage regulation, etc.). Second, model validation by the manufacturers is often incomplete, not available, or difficult to translate to real projects (different settings or software versions, design of the collector system, etc.). In some cases, these difficulties have lead Hydro-Québec to build its own models (see Hypersim section below).

General validation test program

Since 2006, Hydro-Québec has performed validation tests on WPP connected to its transmission system and a general validation test program was established in 2009.[28] The power producer has the obligation to perform validation tests in order to demonstrate that its facilities meet the Transmission Provider requirements. The purposes of this program are:

1. To demonstrate that WPP meet the Transmission Provider technical requirements related to wind generation;
2. To validate numerical models and parameters associated with the WPP, specifically those given to the Transmission Provider by the power producer, by comparing the model response to recordings taken during field tests;
3. To confirm the electrical data of power producer facilities.

The validation program is divided into seven functions to be validated:

1. Primary voltage regulation

[28] http://www.hydroquebec.com/transenergie/fr/commerce/pop_raccordement_transport.html

2. Undervoltage response (LVRT)
3. Inertial response
4. Secondary voltage regulation
5. Power factor
6. Maximum ramp rates
7. Power quality

The tests for the primary voltage regulation are performed on a single WTG and consist in producing instantaneous voltage variations of low amplitude on the terminal of the WTG and small voltage steps of limited duration injected directly into the WTG voltage control system. Three-phase voltages and currents are recorded at the wind generator to measure the local dynamic response of a wind generator to a rapid voltage change and to verify that the response meets voltage regulation requirements. The results are also used to set the model parameters (time constant and gain) used in dynamic simulations. The tests regarding the secondary voltage regulation are similar but are conducted for the entire power plant.

The validation test program includes LVRT tests on one generating unit to verify that requirements during undervoltage conditions are met. The power producer has the responsibility to conduct the tests or to provide a complete report describing tests performed on an identical generating unit (same software version) to demonstrate that the requirements are met. So far, no LVRT tests were performed on site on WPP integrated on the Hydro-Québec network. However, monitoring equipment has been installed at three locations in wind plants: at their point of interconnection, on a 34.5 kV feeder of the collector system and on one generating unit. The monitoring system records signals either continuously or upon detecting variations occurring at the point of interconnection: active power variations, voltage sags and swells and system frequency excursions. These signals are primarily voltages and currents but may also be mechanical variables or other signals.

The field recordings recorded on the network can thereafter be used to validate the dynamic response of the models. This is a time consuming effort that requires the collaboration of the manufacturers to modify the models if necessary. Event recordings to-date have made possible suitable validation of two Hydro-Québec Siemens PTI PSS®E models and one ElectroMagnetic Transients Program (EMTP) model.

Inertial response requirements were not in defined for the projects started before 2005. Consequently, existing wind plants do not have to fulfill them. However, the requirements have to be met for WPP to be commissioned in 2011 and after. The corresponding validation tests consist in emulated frequency steps and ramps of limited duration. Besides verifying the

requirements, the test results will be used to validate the parameters of the models and their dynamic response.

The power factor and the maximum ramp rates modules are tested with all WTGs in service to verify that the requirements are met. Power factor tests consist in supplying and absorbing a maximum amount of reactive power at different levels of active power. Maximum ramp rate tests consist in performing a power plant shutdown sequence followed by a startup sequence. These tests are not really used to validate the models but are rather helpful to fix model parameters.

The last module regarding the power quality is not covered by scheduled testing but by means of a monitoring system that verifies harmonics and emission limits. The recordings are compared to the report provided by the developers to verify if the requirements are met. However, they are not useful to validate the EMTP model since the WPP is represented by a single-wound generator and does not simulate the detailed collector bus system and individual wind turbine generators.

Field tests department

Hydro-Québec field-testing department (UMES) conducts a wide range of special tests and measurements for Hydro-Québec and has done so for 30 years.

To test WPP, UMES installs a monitoring systems to record three-phase voltages and currents generally at three locations within the plant: at the point of interconnection, at the starting point of a 34.5 kV feeder of the collector system and at the terminals of a WTG connected to the same monitored feeder. For extended model validation, other signals within the wind turbine are monitored including the rotor side converter voltages and currents, the network side converter currents, and the DC bus voltage.

High speed recorders with anti-aliasing filters are used. Normally, the sampling rate is 5 kHz with at least a 200 second window per event. The monitoring system is reachable via an Ethernet connection for remote trigger and data retrieval. UMES has also the responsibility to perform the data processing and analysis of the recordings in order to verify the compliance with the interconnection requirements and to extract relevant data for model validation.

Hypersim

The Hydro-Québec Research Institute (IREQ)[29] also has an important expertise in control system and wind generation modeling for extensive studies of electrical networks. The simulation environment used is Hypersim, a real-time simulator and powerful simulation tool that uses a highly detailed representation of the Hydro-Québec network. A full-transient detailed model of a Type 3 WTG was developed at IREQ using the MATLAB® SimPower Systems Toolbox. The model was also implemented in EMTP and in the Hypersim real-time simulator.[30] This model is in the process of being validated with data processed by the UMES team. The range of events recorded does not make it possible to validate the model completely and the design and parameters will continue to be adjusted to improve the representation of the wind turbines. The validation of the MATLAB® model developed by IREQ was very useful to validate and improve Hydro-Québec's Siemens PTI PSS®E user model.[31]

4.2.2 GE Example – based on GE's work with client facilities

In the case of the first example presented here, a 10 MVar capacitor bank, located at the 25kV WPP collector bus, is switched off-line as an external physical stimulus. Figure 4.1 shows detailed response to capacitor switching from the WindCONTROL®. The WindCONTROL® system allows coordination of all on-line turbine-generators for plant-level fast and smooth voltage regulation at the point of interconnection (POI), located contractually at the 25kV substation bus. The red curve (Q_ACTUAL [KVar]) shows that total plant reactive power initially drops after the switching action, but the fast autonomous controls on each turbine generator quickly and stably respond to increase reactive power generated by individual turbines, shown by the orange curve (Q_TURBINES [KVar]). The WindCONTROL® command (Q_CMD) distributed to the turbines is shown in blue. The response of Q_CMD is dominated by the gains of the voltage regulator portion of the WindCONTROL®, specifically the proportional gain, K_{pv}, and integral gain, K_{iv}. The difference between the response of the individual turbines (Q_TURBINES [KVar]) and the WindCONTROL® command (Q_CMD) is due to the dynamics of the individual wind turbines. The coordinated response of the wind plant and the individual

[31] C. Langlois, D. Lefebvre, L. Dube and R. Gagnon, "Developing a Type-III Wind Turbine Model for Stability Studies of the Hydro-Québec Network," in Proc. 8th International Workshop on Large-Scale Integration of Wind Power into Power Systems, Bremen, Germany, Oct. 14-15, 2009.

turbines is multi-modal: a fast initial response to address severe perturbations as well as a slower, grid friendly refinement. For purposes of this test, the automatic control of the capacitor bank by WindCONTROL® was disabled and manual switching was used as a stimulus to record individual WTG response.

The detailed plot in Figure 4.2 shows a zoomed view of the response to step change in voltage at the WTG. The very fast initial response will dominate and saturate the controls for big events. The wind plant will do everything as quickly as it can to mitigate a large disturbance. In this case, the fast response took approximately 200 milliseconds. The slow, refined control then takes over to allow for coordination with other equipment and maintain post-disturbance stability. This aggregate response also allows for a very abrupt action when needed, and a grid-friendly refinement that maintains stability in less severe cases.

The green curve in Figure 4.3 shows that when the capacitor is switched off-line, the measured voltage at the point of interconnection (or POI) decreases due to reduced reactive power flowing into the grid. The response of the individual WTGs is to rapidly increase reactive output to make up for the loss of reactive power supplied by the shunt capacitor. The plant level control then responds to this initial under-voltage condition and attempts to restore the POI voltage by increasing each wind generator's reactive output by equal amounts until the plant voltage settles to the control set point determined by the operator. The lower traces in Figure 4.3 show a gap during the period when the capacitor bank is online between total plant Q (Q_ACTUAL) and summation of Q out of each WTG (Q_TURBINES). This gap represents the capacitive reactance added by the shunt bank. When the capacitor is switched offline, the gap between Q_ACTUAL and Q_TURBINES closes and all reactive power is supplied solely from the WTGs. The initial loss in plant reactive power is mitigated within approximately 15 seconds as each WTG settles to a new, increased level operating point of reactive power. This new, increased reactive level for each WTG, is the total Q increase from all units on-line in the plant, divided by the total number of units online at the time of the test.

Figure 4.4 shows a comparison between these measured values and the simulation results of the PSLF model. Model outputs Q_g, Q_{plant}, Q_{cmd} and V_{reg} correspond to measured Q_TURBINES, Q_ACTUAL, Q_CMD and U_LINELINE respectively. This plot shows the model performance adequately represents what is happening in the field. The response matches closely, with a difference immediately following the switching operation being due to lower sampling rate in the measurement than in the GE PSLF® simulation.

Response to grid events demands relatively rapid control action. Manual grid or plant operator changes in operating set-points do not normally demand fast response, and indeed, system behavior ought not to be rapidly disturbed by moving set-points. Figure 4.5 shows the response of GE plant to 2% step in voltage reference. The blue trace in the figure shows a well mannered response to the reference step. The red trace is from the simulation model, which matches very

well. In the blue trace, after, the perturbation occurring about 8 seconds after the reference change the plant supervisory control switched on a shunt capacitor to retain dynamic range on the wind turbines. The switching perturbation is rapidly balanced by the turbines, allowing the response to continue smoothly.

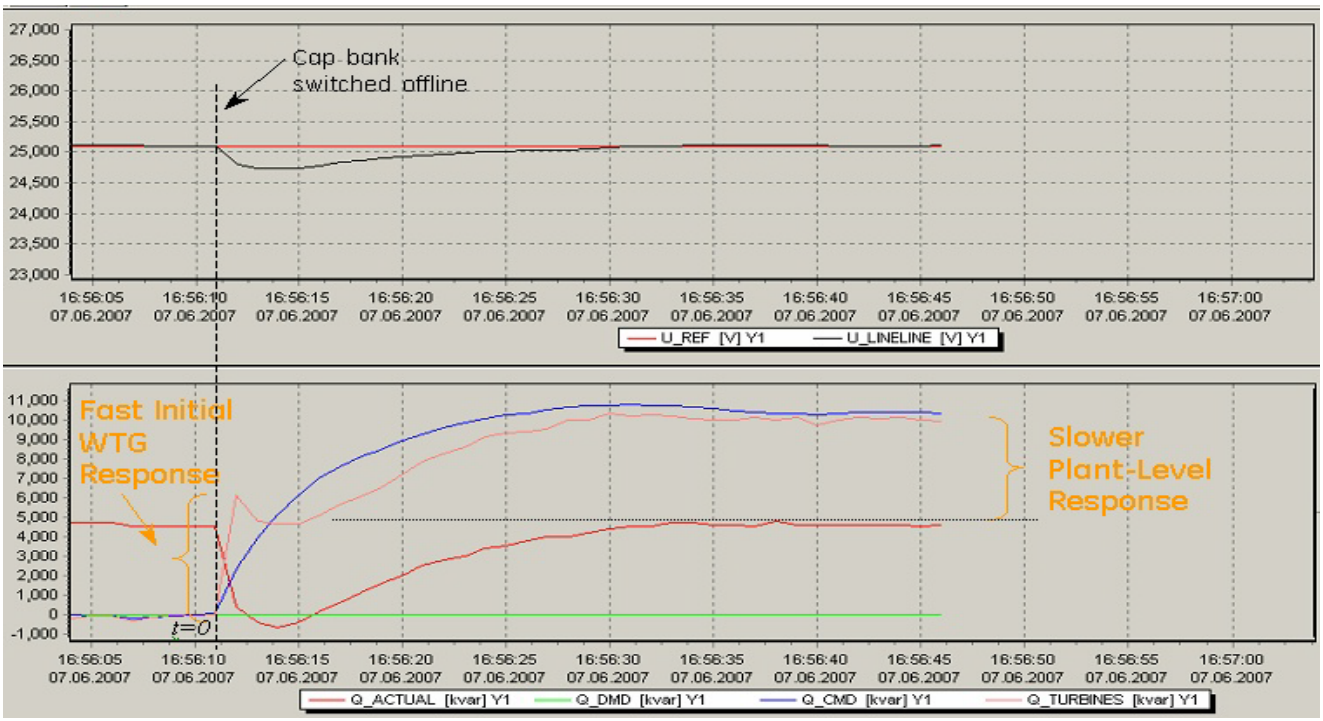

Figure 4.1: 10 MVar Capacitor removal response measured from WindCONTROL®.

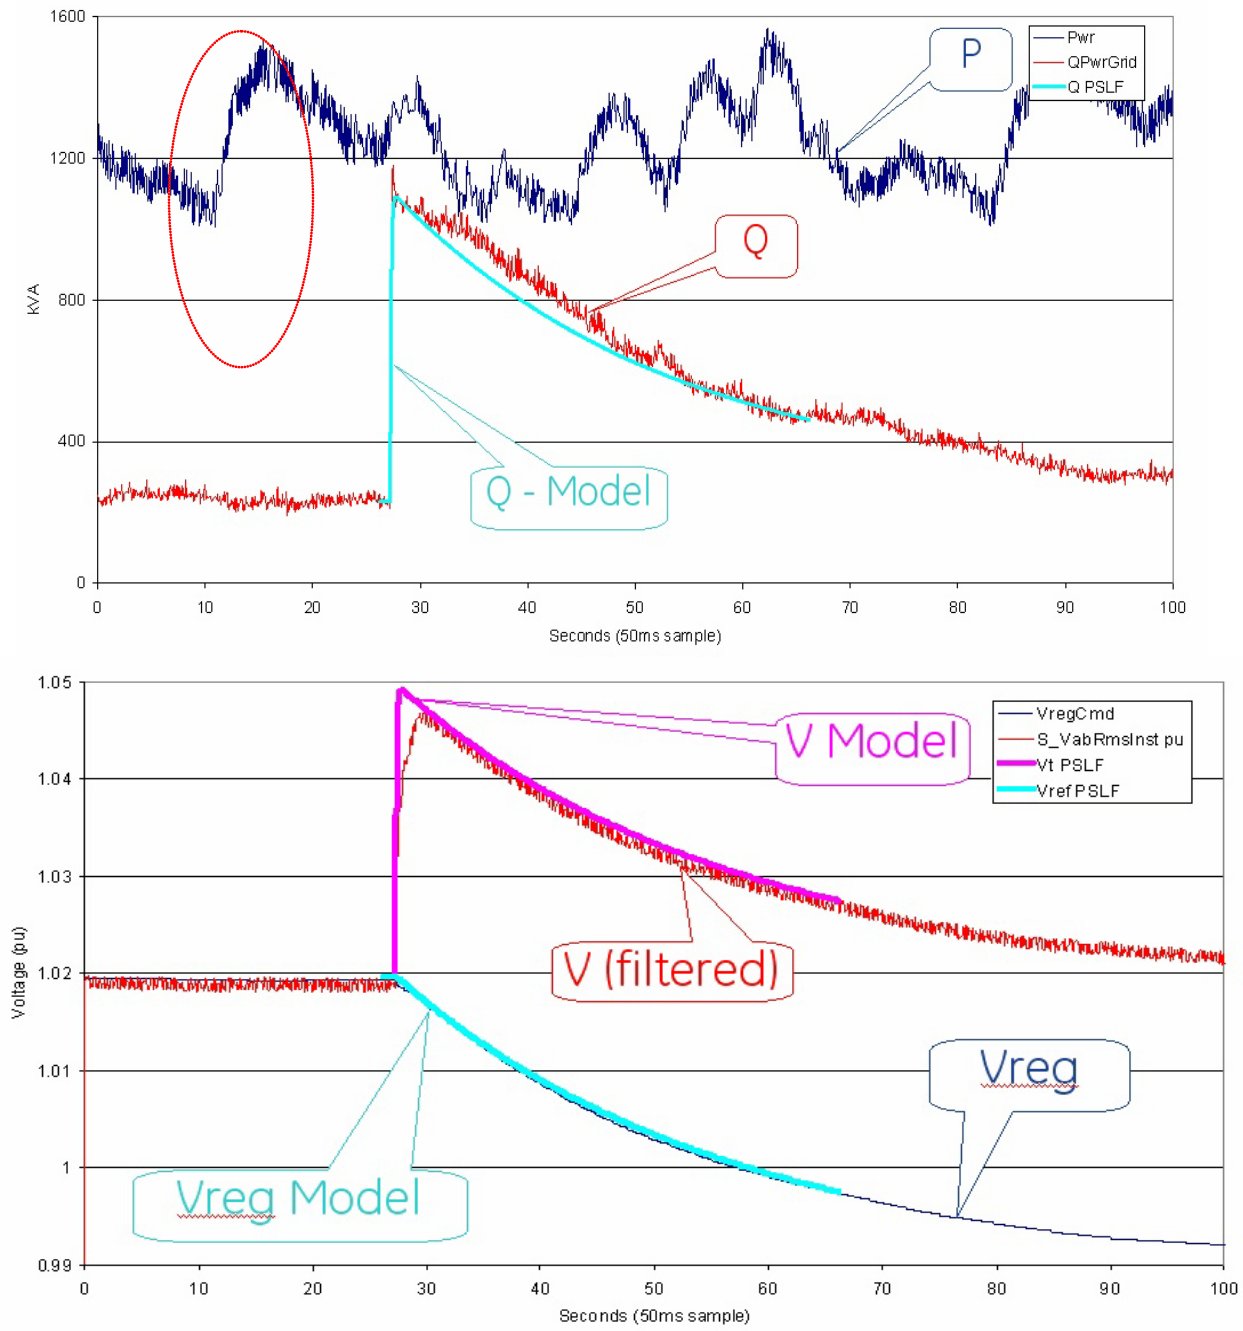

Figure 4.2: Wind turbine-generator level voltage step test response

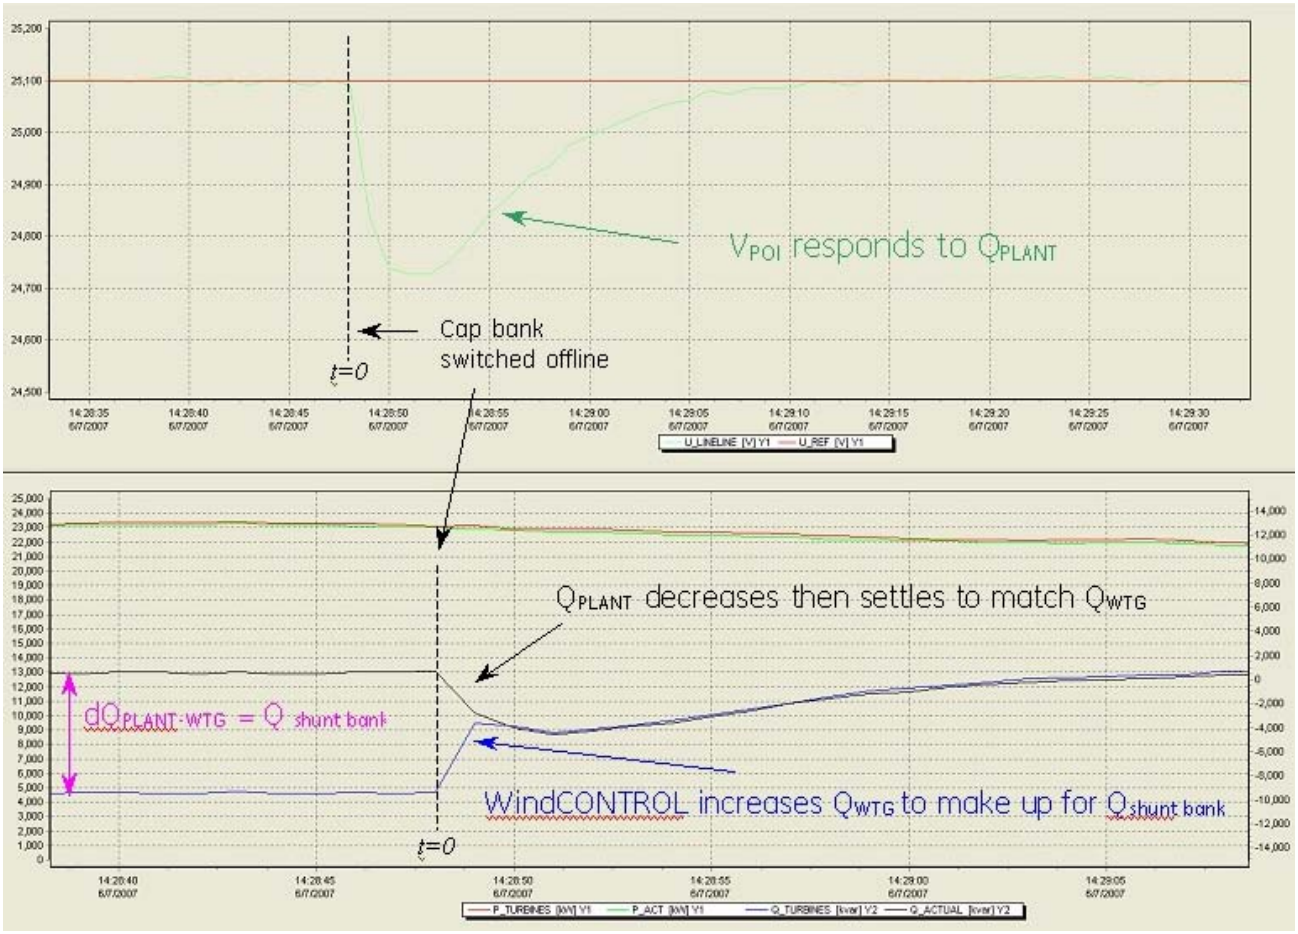

Figure 4.3: 10 MVar Capacitor removal response – POI variables.

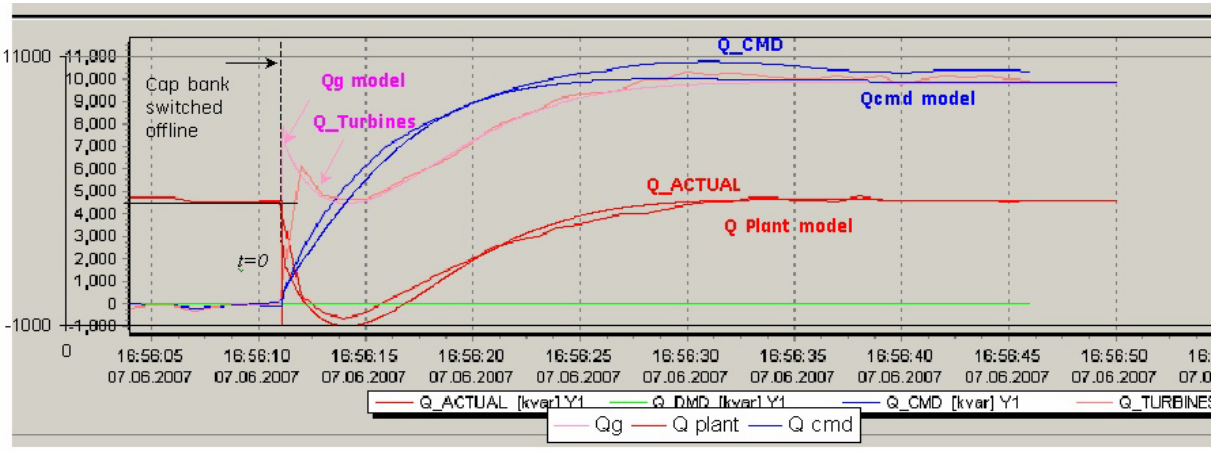

Figure 4.4: 10 MVar **capacitor removal field test vs. simulation results**

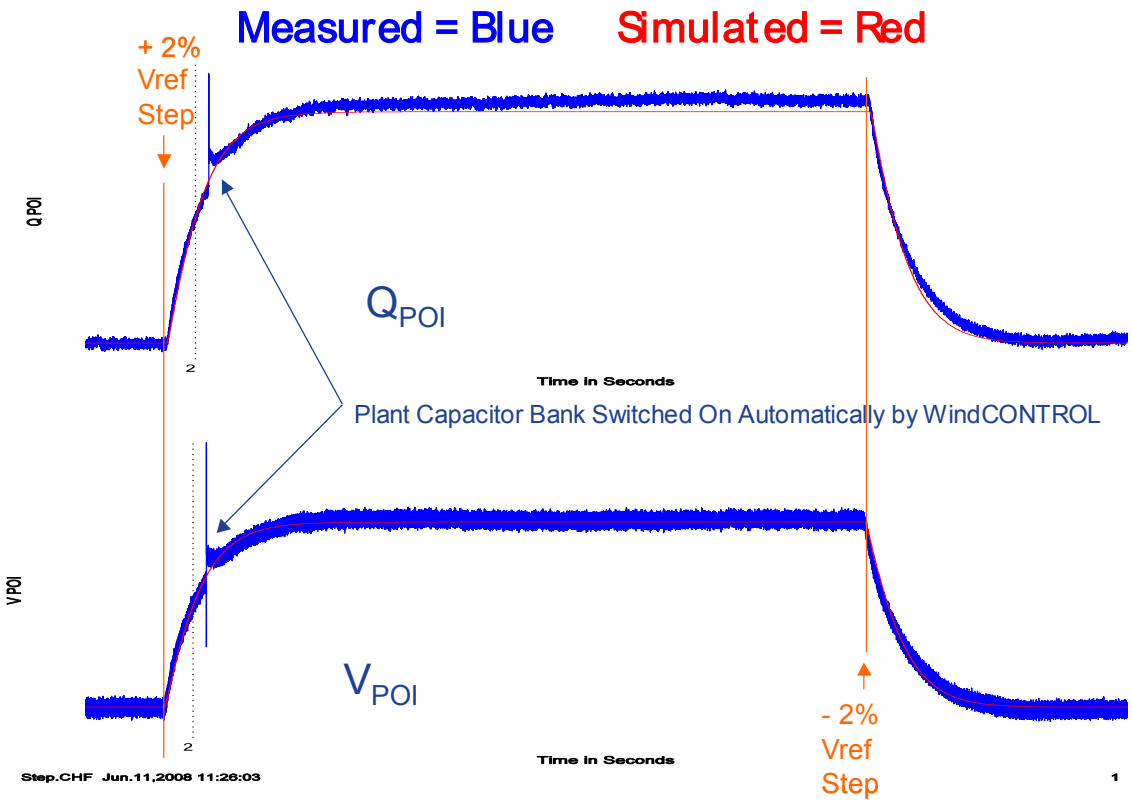

Figure 4.5: A different step test. +/- 2% step of voltage reference

The performance for grid fault events is of considerable interest in system planning. Staging faults, particularly severe ones on operating wind plants, is difficult and expensive. Figure 4.6 shows a comparison between a staged fault test and the (present) Siemens PTI PSS®E model of the GE 2.5 (full converter) WTG. The fault event is quite severe: a 3-phase 700ms of voltage depression to less than 20% of nominal at the high voltage terminal of the WTG unit transformer. The measurement traces (on the left) include some of the signal noise characteristic of measurement and extraction of fundamental frequency positive sequence information from real, high resolution measurements. The simulation traces on the right, are, of course, cleaner. The match between test and simulation is of very high fidelity for phenomena relevant and legitimately examined with positive sequence simulation tools (i.e., greater than one cycle).

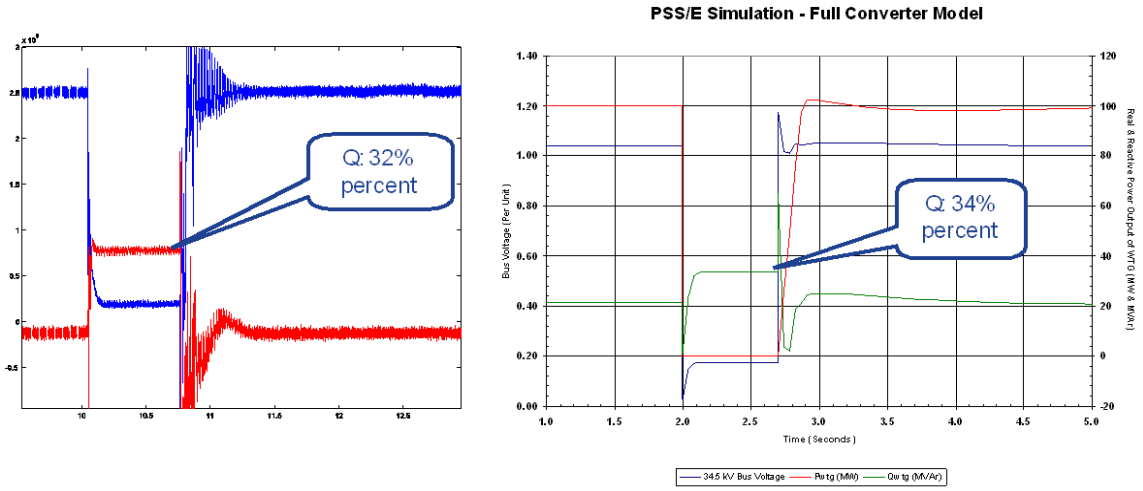

Figure 4.6: GE 2.5 WTG Fault Test vs. PSS/e Model Performance

The discussion provide above is solely geared to hardware testing and validation, however, another highly valuable and legitimate means of providing validation of simulation models (for planning and otherwise) is to use more complex simulation software to validate simpler planning models. Manufacturers normally have highly complex, and highly proprietary, models of their equipment. These models are used, among other things, to design equipment and are normally physically based and must have sufficient fidelity for original equipment manufacturers (OEMs) to make sound engineering judgments for equipment design and application. The OEMs are highly motivated to have these detailed high fidelity equipment level models. These detailed models therefore can often be used to design, test and validate simpler planning models to be used by the industry.

There is a long, accepted history in the power industry of this practice. For example, a typical (GE) gas turbine has on the order of 4,000 state variables in the design model; planning models typically have on the order of four state variables: simplification is necessary and expected. These design codes have been used to develop planning models of gas turbines. Figure 4.7 below shows a comparison between a fault simulation using a GE design code (GE WindTrap®) and the planning model in GE PSLF® for a GE 1.5 (double fed machine) WTG.

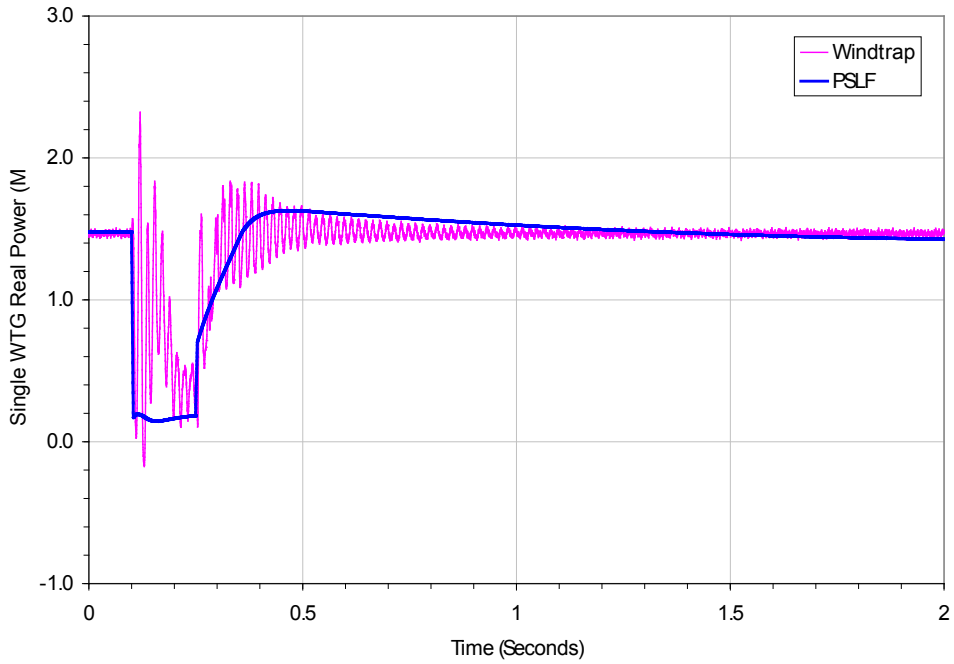

Figure 4.7: Detailed Design Simulation (GE WindTRAP®) vs. GE PSLF® Model Performance (active power during a severe fault for a GE 1.5 WTG)

5. Summary & Recommended Actions – Standards Implications

This document has presented a general overview of modeling and model validation as it pertains to variable generation resources. Clearly, to date, the bulk of the experience and work has been on wind turbine generators. Never-the-less, similar approaches for modeling and model validation are being pursued for other variable generator technologies such as PV.

Non-proprietary and publicly available models for the simulation of steady-state (power flow), short-circuit (fault calculations) and dynamic (time-domain simulations) behavior of such generation resources must be made readily available for use by power system planners. Furthermore, these models should be routinely validated to ensure proper representation of variable generation power plants in bulk power system studies. A model is valid if its dynamic behavior is close enough to reality so that its influence on the network of interest (i.e. used for power system studies) is consistent with the fidelity of model structures and available data for the power system and other generation, as it pertains to the phenomena of interest (i.e. in stability studies). That is, perfect curve fitting is not necessary, but to the extent possible erroneous model dynamics must not result in a notable over-design or under-design of the network.

Each of the NERC standards discussed below in Section 5.2 address to aspects of meeting a standard: (i) the technical requirement, i.e. the need to define, measure validate a model, its parameters etc., and (ii) the procedural requirements, i.e. the functional model of how this technical requirement should be met, reported and monitored. The bulk of this working group's recommendations stated below address the technical requirements. Variable generation is a new and quickly evolving technology and consideration should be given to the timing with which standards be implemented.

Section 5.1 below first gives a summary of the planning process based on NERC standards to put the discussions in this report into context with the NERC standards. Then in Section 5.2 we provided our recommendations and comments on the NERC existing and developing standards.

5.1. Applying the NERC Standards

The NERC standard FAC-001 (see Figure 5.1) should be expanded to clearly cover modeling requirements during the coordinated joint study phase of the Facility connection process. Simple generic models of variable generation may be adequate for the IES phase and more detailed models may be needed for the IFS phase. Validation of the simple and detailed model parameters may be needed during commissioning.

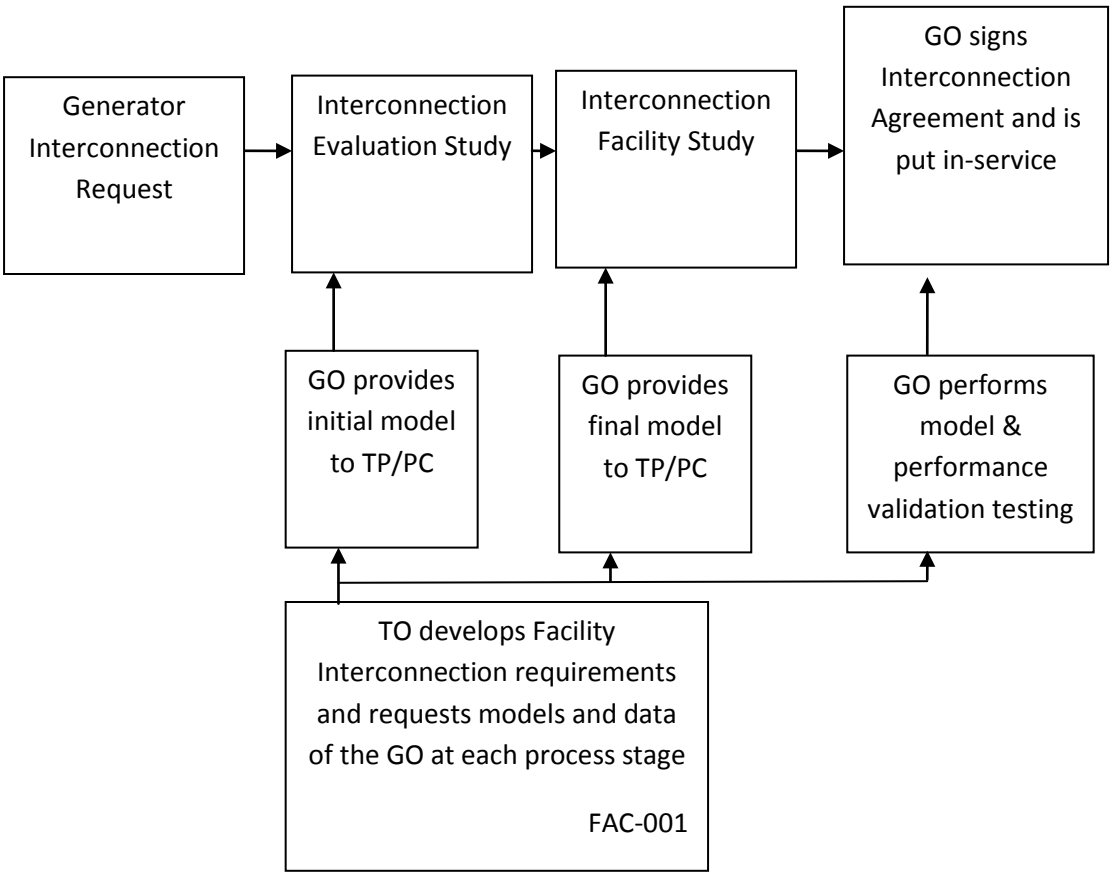

Figure 5.1: Facility connection process.

The generic model with associated parameters feed into the NERC model building process shown in Figure 5.2. As an example, for WTG, presently there is insufficient evidence of the accuracy of presently available generic models for WTG[32] for all the various WTG manufacturers. Some confirmation tests during commissioning or type tests or comparison simulation tests with a detailed model are necessary to get buy in from the Transmission Owner/Planner. As the technology matures, and generic models are enhanced, and associated data parameter sets are developed for specific machine types, the new generic models will become more accepted as is the case with models of hydro or thermal plants.

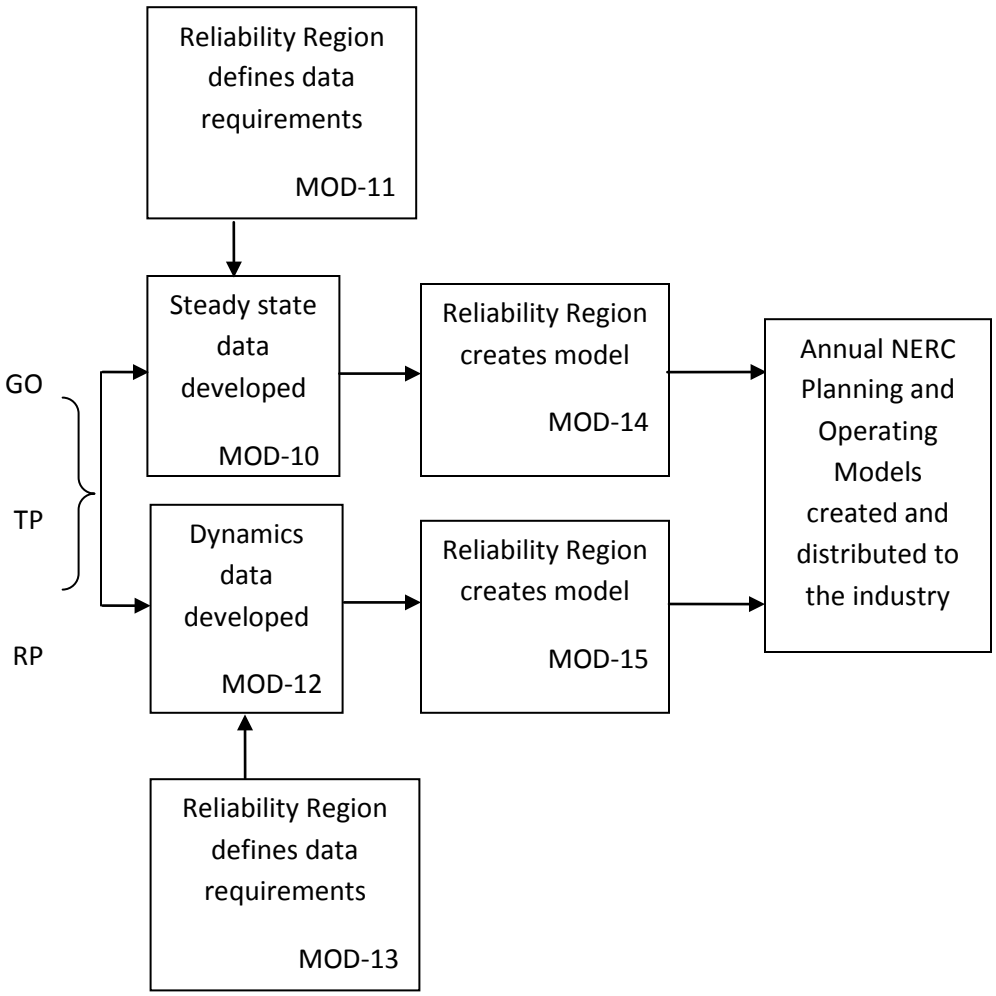

Figure 5.2: Annual NERC Model Development Process

PSS®E-32.0 Model Library, Chapters 17 through 21
GE PSLF User's Manual. v.17.0_04. October, 2009.

The regional model building manuals developed as part of MOD-11 and MOD-13 must provide sufficient clarity to model variable generation. These manuals may ask for best available models or generic models. These models cover the operational time frame and the 10-year planning horizon. The manuals do not currently cover the frequency for revalidating model data.

While not included in the standards, more emphasis is currently being placed on meeting the Eastern Interconnection Reliability Assessment Group (ERAG) model building manual requirements in addition to regional requirements.

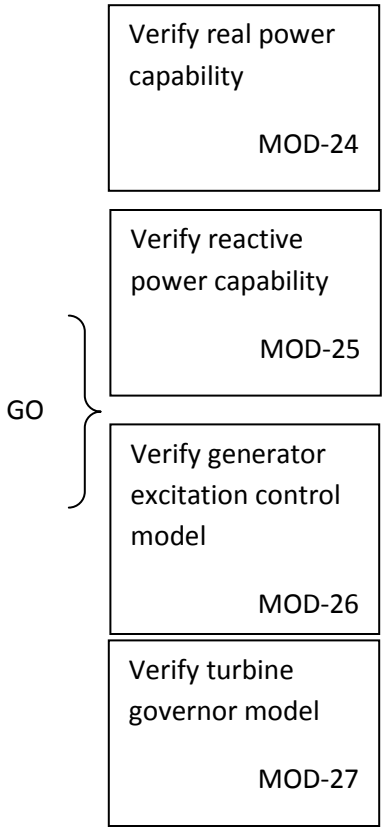

Figure 5.3: NERC Model Validation Process

The Regional Entities develop the test procedures and dictate testing frequency for the Generator Owners to follow. The model data then feeds in to the annual NERC model building process.

5.2. NERC Standards Technical Issues

One general comment is that the NERC Glossary of Terms would benefit from the term "Variable Generation" being include in it and appropriately defined. A suitable definition can be found in the Phase I report of the IVGTF.

MOD-011: Regional Steady-State Data Requirements and Reporting Procedures

The technical requirement in this MOD reads:

> "R.1.2 Generating Units (including synchronous condensers, pumped storage, etc.): location, minimum and maximum Ratings (net Real and Reactive Power), regulated bus and voltage set point, and equipment status."

This statement could be read to equally apply to variable generation as a source of generation. However, it may be prudent to explicitly include variable generation in this statement. For example, to change the sentence to:

> "R.1.2 Generating Units (including synchronous condensers, pumped storage, ***variable generation resources*** etc.): location, minimum and maximum Ratings (net Real and Reactive Power), regulated bus and voltage set point, and equipment status. ***For variable generation a suitable aggregate steady-state model of the collector system and equivalent unit representing the full plant.***"

MOD-012: Dynamics Data for Transmission System Modeling and Simulation

This MOD equally applies to variable generation and needs no augmentation. The requirements in the MOD are quite generic. The requirements of this standard are dependent on and point to MOD 13, discussed below.

MOD-013-1: RRO Dynamics Data Requirements and Reporting Procedures

This MOD explicitly discusses synchronous type generation. It would be beneficial to include an explicit statement to cover variable generation. For example,

> "Plant-specific dynamics data shall be reported for variable generating units (e.g. wind turbine generators, PV etc.) such as the type of generating unit, its interface with the grid and the appropriate model and model parameters to adequately represent unit dynamic response for bulk power system studies. The typical size of a single variable generating unit (e.g. wind turbine generators, PV array, etc.) is several hundreds of kilo-watts to several mega-watts. Thus, it may be acceptable for the total plant to be represented by an adequate aggregated model of the collector system and a single equivalent generating unit scaled up to represent the total name-plate capacity for each type of generating technology employed in the plant. Furthermore, models may need to be provided for other equipment installed in the collector system or at the point of interconnection such as reactive compensation devices."

MOD-024-2 — Verification and Data Reporting of Generator Real Power Capability

This latest posting of this MOD, posted for commenting on January 18th, 2010, exempts variable generation from this requirement. It states:

> "Variable energy units such as wind generators, solar, and run of river hydro are exempt from the requirements of this Standard."

For a variable generation plant the definition of Real Power Capability can be slightly challenging. One way to view it is to see the total gross capability as the sum of the nameplate rating of all individual units within the plant, e.g. for a wind power plant the total sum of the nameplate rating of all wind turbine generators in the plant. However, there must be two realizations (i) the amount of actual power injected into the grid at the point of interconnection requires a suitable representation of losses on the collector system and auxiliary loads, and (ii) by its very nature variable generation is a highly variable energy source and thus it is quite rare to find point in time when all units in the plant are coincidentally at their peak nameplate capacity. Finally, the seasonal variable generation output variations need some discussion since they are quite different than conventional generation technologies.

MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability

The technical requirement in this MOD reads:

> "R1.5. Information to be reported:
>
> R1.5.1. Verified maximum gross and net Reactive Power capability (both lagging and leading) at Seasonal Real Power generating capabilities as reported in accordance with Reliability Standard MOD-024 Requirement 1.5.1.
>
> R1.5.2. Verified Reactive Power limitations, such as generator terminal voltage limitations, shorted rotor turns, etc.
>
> R1.5.3. Verified Reactive Power of auxiliary loads.
>
> R1.5.4. Method of verification, including date and conditions."

Note: the above requirements are from the existing version of the standard. MOD-025 is currently being enhanced.

Although all of the above could equally apply to variable generation, some clarification may be needed. Namely, variable generation reactive capability of the "power plant" is not entirely inherent in the individual generating units. A variable generation power plant, such as a wind power plant, may contain many reactive power sources such as the individual generating units themselves (e.g. Type 3 or 4 WTG, see Appendix I), discretely switched shunt reactive devices

(e.g. shunt capacitors or reactors), smoothly controlled shunt reactive devices (e.g. SVC or STATCOM), or a combination of these devices. Thus, care should be taken as to how the total reactive capability of the power plant is defined and at what point (e.g. point of interconnection, and whether this is defined as the high or low side of the substation transformer). Also, it may not be practical under normal operating conditions to exercise the full reactive capability of the power plant (this is a known issue, even with conventional synchronous generator plants) to test it, thus it should suffice to demonstrate the plants reactive capability to the extent possible in the field and to then augment this with engineering calculations to derive the plants full reactive capability. This is particularly, true of variable generation because there is no control over the energy resource. So for example, a typical wind power plant may only achieve its name-plate rating for a hour or two during an entire year. Thus, it would not be possible to demonstrate the full reactive capability of the plant in the field. Rather, it should suffice to demonstrate the reactive capability of a single WTG and then to derive through engineering calculations (considering all other reactive devices in the plant, such as SVC, STATCOM etc.) the total reactive capability of the plant. These comments should be somehow used to appropriately modify MOD 25.

MOD-026-1 — Verification of Models and Data for Generator Excitation System Functions – SECOND POSTING (and MOD 27)

MOD 26 (and MOD 27 *Verification of Models and Data for Turbine/Governor and Load Control*) are presently under development[33]. These two standards deal specifically with the routine validation of generating unit dynamic models for power system stability studies.

Presently, these standards are tailored explicitly to deal with synchronous type generators, since much of the language revolves around technology associated with synchronous generation (e.g. excitation system, AVR, power system stabilizers etc.). Thus, the following key items need to be clarified in these standards, as they pertain to variable generation. In addition, the comments that follow apply to all components in a variable generation plant that may include devices such as the actual power generating units, shunt compensation devices, centralized control systems spanning the entire facility, etc.:

1. Unit/Plant Size for Validation: These MOD's specify the size of generating unit above which model validation is required. It should be recognized that the typical size of a

[33] MOD 26 and MOD 27 standards under development are found at http://www.nerc.com/filez/standards/Generator-Verification-Project-2007-09.html.

variable generation unit is in the hundreds of kilo-watts to several megawatts range. Thus, the language should be changed (or introduced) to indicate "net power plant" size.

2. Validation of various technologies in a single plant: Variable generation power plants can consist of multiple generation technologies. For example, a wind power plant may consist of WTGs of two different types. Thus, we need to consider the following points as they pertain to variable generation:

    a. For a uniform variable generation plant (i.e. all generating units are of the same technology type) a single aggregate generator model representation should be sufficient.

    b. For a significantly diverse variable generation plant, the plant should be represented by multiple aggregated unit models representing each technology type.

    c. Unique representation of a group of variable generation units as a single aggregated generator model representation should be based on:

        i. The size of the group is a significant proportion of the total plant size (e.g. > 20% of plant rating).

        ii. Each group should represent a unique characteristic (e.g. Type 1 WTG as compared to a Type 3 WTG).

3. Validation of different control layers: Variable generation plants, such as wind power plant, may have several functional layers of control. For example, in a wind power plant with Type 3 WTGs we may have one level of closed loop voltage regulation at the terminals of the WTG, a second slower control loop that regulates voltage at the point of interconnection (POI), and a third layer of control that coordinates the switching of shunt capacitors at the POI based on the reactive output of the individual WTGs. In addition, devices such as STATCOMs may be present at the POI. Modeling and model validation should incorporate such devices/control layers to the extent that the dynamics of these functional layers are important for stability studies (see Figure 3.1).

4. Modeling and Model Validation: Models are an emulation of actual equipment. Not all model parameters necessarily translate to actual physical components or measureable features. Judgment needs to be exercised in the modeling and validation process.

    a. Models should be validated typically against the performance of an actual plant for a given event/disturbance, within the given operating range it is designed for.

b. Models should state clearly the type and the range of events they have been designed to simulated and the limitation of the models beyond which the model deviates from the actual variable generation plant performance (e.g. a model developed to represent electrical transient behavior of a WTG may not be adequate for studying wind fluctuations over a many minute time frame).

c. In general, the best approach to model validation is to use field (or test bench) measurements of various disturbances that must exercise the different control functions to a wide range of operation points. For example, a model is not necessarily valid if the only a comparison between simulation results and field measurements for a single voltage step response is performed at one operating condition. Ideally, illustration of validation against recorded response to various system disturbances (faults, frequency deviations, etc.) gives the greatest confidence in validation.

d. A model is valid if its dynamic behavior is close enough to reality so that its influence on the network of interest (i.e. used for power system studies) results in relatively negligible errors for the phenomena of interest (i.e. in stability studies). That is, perfect curve fitting is not necessary, but to the extent possible erroneous model dynamics must not result in a notable over-design or under-design of the network.

5. Future functionality: Due to the rapidly evolving nature of variable generation technologies, variable generation models should be of a modular nature, such that future functionality can be incorporated, as much as possible, into old model structures by adding a functional modular block. For example, presently Type 3 and 4 WTGs do not exhibit inertial response. However, at least one manufacturer now supplies a functional control addition that can emulate inertial response on these units. Such functionality is likely to be made available soon by most vendors. Thus, a functional model block can be developed that can be added to the existing models for Type 3 and 4 WTGs to emulate the behavior of this additional control.

6. Modeling of protection: Variable generation, much like conventional generation, will have associated under/over voltage and under-over frequency protection. These should be modeled. Attention should also be given to protective relay coordination with plant controls, particularly in light of the nature of the grounding system within the variable generation plant (e.g. a wind power plant spans an entire collector system, which can be grounded in several different ways and thus have various implications on protective relay coordination). Such coordination issues relate to the PRC and FAC-001 standards.

7. Issues related to the fuel source for variable generation: For variable generation one needs to be cognizant of the variable nature of the energy source and thus the possible impracticality of performing model validation at a desired plant output, but rather having to accept model validation at whatever plant output can be achieved at the time of testing or disturbance monitoring.

8. Revalidation: How often should models be revalidated?

    a. Many variable generation technologies are rapidly changing, for example in wind power plants new control software or new setting may be uploaded every year, if not sooner.

    b. If the changes are insignificant, the existing dynamic models should be revalidated if possible as a matter of prudency – say within six months or so of a control system update/upgrade. The changes (in parameters or dynamic model) should be reported to the local Reliability Entities.

    c. If the changes are significant, the existing dynamic models should be revalidated – say within three months or so after the update/upgrade. The changes (which may include a new module, new software etc.) should be reported to the local Regional Entities.

5.3. Final Recommendation

An earlier draft of this report and recommendations were presented to NERC's Planning Committee at their March, 2010 meeting. The Committee members urged the IVGTF to pursue NERC reliability standard development. Thus, several NERC Standards Drafting Teams undertaking MOD Standard development will be contacted to present the recommendations from this report for their consideration and incorporation in subsequent updates. The standard drafting teams for MOD-026 and MOD-027 are aiming to incorporate variable generation considerations in the next release of these draft standards.

Attachment A – Standard Drafting Team Members 17

Introduction

The Project 2010-05.2 – Special Protection Systems Standard Drafting Team (SDT) developed this background and Frequently Asked Questions (FAQ) document to explain the key concepts incorporated into the revised definition, as well as the team's approach and intent. This document will remain available as part of the official project record for the Remedial Action Scheme (RAS) definition. The drafting team has updated this (FAQ) document to reflect all revisions made to the RAS definition based on stakeholder feedback.

Contact the NERC Standards Developer, Al McMeekin, at 404-446-9675 or at al.mcmeekin@nerc.net with any comments or questions.

Background Information Regarding the Definition of RAS

Section 1. Design and Maintenance Requirements

Section 2. Study and Documentation Requirements

Section 3. Operational Requirements

Section 4. Analysis of RAS Operations

Why was the Reliability Coordinator chosen to perform RAS reviews? [Gene]

The FERC directive (753? Re: PRC-012, PRC-013, PRC-014) that rejected the Regions as acceptable entities for responsibility under NERC Functional Model and standards identified that the proper entity(ies) must have Planning or Operating responsibilities within the NERC Functional Model. The NERC white paper suggested either the PC or RC for the review responsibility. The Regions have as many as 30 PCs for one RC, though other Regions have a single PC and RC for the Region. Overall, there are 15 RCs and about 80 PCs. Since this standard needs to apply across North America, the Reliability Coordinators clearly have the widest possible view of the System of any Operating or Planning entity.

The RCs have corporate independence from RAS owners, while PCs in some Regions often are effectively subsidiaries of a RAS owner. Such PCs could not effectively perform an independent review of any RAS proposed by their owner.

The SDT considers the RC as the FM entity most likely to represent the reliability interests of independence, wide geographic oversight, and continuity characteristic of the present RRO administered reviews. The SDT considers the RC as unlikely to be a stakeholder in any given RAS and thus is a sufficiently independent FM entity to conduct the reviews. In many instances the RC geographic oversight exceeds that of the respective PCs. The larger RC geographic oversight will minimize fragmentation of the present RRO administered reviews.

With regard to the need for multi-disciplinary expertise, the RC may designate another entity to conduct the review per the checklist in Attachment 2 if the RC does not believe it has the necessary qualifications itself. The present assignment to the RROs may continue under this standard should the RRO agree to continue the review function at the request of the RC(s). Continuity may be assured by institutionalization of the review panel within a RC or RRO area.

Why are Planning Coordinators not required to perform annual evaluations of RAS performance? (Gene)

TOP-005-1_R3 requires BAs and TOs to perform operational reliability assessments (e.g. RTCA, day ahead, seasonal), which includes data describing new or degraded special protection systems [RAS]. In addition, IRO-005-1_R12 requires that RCs must share any pertinent data, such as SPS [RAS] with potentially affected BAs and TOs. Short- to medium-term operating assessments that include RAS are already required by other standards, so an additional requirement duplicating that effort is not necessary.

TPL-001-4_R2 also requires the TP and PC to perform annual Planning Assessments of the Near-Term Transmission Planning Horizon. R2.7.1 acknowledges that new, modified, or removed SPS [RAS] may be part of a CAP used to fulfill Table 1 performance requirements. Planning horizon annual assessments are already required by the TPL-001-4 standard, including RAS, so an additional requirement duplicating that effort is not necessary.

Why is the 5-year evaluation/assessment assigned to the Transmission Planner, rather than the Reliability Coordinator? [Bobby]

Why were the Regional Entities not included as part of the review process? (Gene)

FERC directive (753? Re: PRC-012, PRC-013, PRC-014) rejected the Regions as acceptable entities for responsibility under NERC Functional Model and standards. FERC indicated that proper entity(ies) must have Planning or Operating responsibilities within the NERC Functional Model. Regions are not Planning, Operating or Owning Entities in the NERC Functional Model, so cannot have responsibilities assigned to them by the standards.

Why do RAS need to be reviewed by a group other than the RAS owner? (Rob)

RAS are unique and customized assemblages of various protection and control components that do not conform to any standardized or otherwise typical or customary utility practices. As such, they have a potential to introduce serious reliability risks if not carefully planned, designed, and installed. While a RAS may be installed to address a reliability issue, or achieve an economic or operational advantage, it might also introduce other reliability risks that may not be apparent to a RAS entity focused on the issue or advantage at hand. Any such unforeseen risks need to be identified, and a review by a multi-disciplinary panel of SMEs is the best means to identify such RAS introduced risks and recommend RAS modifications where necessary.

Why is RAS approval required as part of the outside review? (Amos)

RAS approval is required as part of the outside review because it is the measure for which evidence of a review occurred. An approval shows that the RAS (new, modified, or retired) has met the minimum requirements of Attachment 1. As part of the process to get approval, the RAS has been coordinated with other entities through the review process and approval of which is indicative that all issues have been resolved including coordination issues.

Why was a continent-wide review entity not prescribed? (Gene)

Reviews limited to specific areas are difficult enough to identify an appropriate reviewing entity. No appropriately skilled continent-wide body presently exists. Some familiarity by the reviewers with the area electric system pertinent to each RAS is very useful to promote an effective and efficient RAS review process, which would be much more difficult for a single continent-wide reviewing entity.

What is meant by "single component failure" and why is it required to mitigate this for Planning Significant and Planning Limited schemes? (Al E. and Gene)

If a RAS is deemed necessary to satisfy the performance requirements of a NERC reliability standard such as, and in particular, TPL-001, it is necessary that its operation under the conditions and events for which it is designed to

operate be assured in the operational realm as well as in the planning realm. Full redundancy of the RAS components achieves this goal. Full redundancy is also consistent with the performance requirements of TPL-001, Table 1, Category P5 where a component (relay) failure of a protection system is combined with a normal planning contingency. The companion consideration associated with the PS redundancy requirement is the assurance of avoiding significant adverse system impacts.

The level of redundancy of a RAS can vary depending on the design characteristics of the scheme, the actions it performs and the conditions it is intended to mitigate. The minimum redundancy level required in Attachment 1 is that "a single component failure in a Planning Significant (PS) or Planning Limited (PL) RAS does not prevent the BES from meeting the same performance requirements as those required for the System events and conditions for which the RAS was designed". The intent of this requirement is to minimize the risk of a RAS not being able to operate as intended if a single component fails to operate. The SDT contends that failure of a single component critical to the correct operation of a RAS has a relatively high occurrence and considers that the level of redundancy of any RAS classified as PS or PL should be such as to minimize this risk. This minimum redundancy level can be achieved by different means, as long as the RAS is designed such that it is capable of performing its intended function while itself experiencing failure of a single component. The most obvious way to obtain sufficient redundancy is to duplicate the components that are crucial to the correct operation of the RAS. For schemes performing action involving like load shedding and generation rejection, over arming can also be an option (i.e. providing more corrective action than necessary to ensure sufficient action in case of single component failure).

What is required for RAS inadvertent operation? (Rob)

What is meant by RAS coordination with other RAS and Protection Systems? (Gene)

RAS are complex schemes that typically take action which trips load or generation or re-configures the system. Many RAS depend on sensing specific system configurations to determine whether they need to arm or take actions. Overlapping actions among RAS would have the potential to result in cascading, unless coordinated. Similarly, RAS reconfiguration of the system changes available fault duty, which can affect distance relay overcurrent ("fault detector") supervision and ground overcurrent protection coordination. A third coordination example is a RAS that detects a line outage as a trigger to action, but delays executing that action until automatic reclosing on the faulted line is attempted and fails. The delay time for the action must be longer than the reclosing open interval on the line. Many RAS are intended to mitigate thermal equipment overloads following outages of other equipment. Typical intended action is shedding of load or generation, or system re-configuration. A small coordinating delay, e.g. up to a few seconds, is required to avoid initiating action while a system fault is present, However a delay of several minutes may be acceptable as long as that is compatible with the thermal characteristics of the overloaded equipment. This may allow operator intervention.

Why do RAS not need to be classified? (Al E.)

Classification of a RAS is necessary to provide a consistent, continent wide framework for reliability risk categorization. The classification categories consider RAS inadvertent operation, and RAS non-operation. The resultant classification will determine the level of requirements proportionate to the reliability risk, the level of Reliability Coordinator review, and the RAS design criteria (redundancy).

Why was "RAS misoperation" not defined? (Gene)

The SDT recognizes that the suggested description of "RAS Misoperation" in the NERC white paper would be a plausible starting basis if a separate definition is needed. However, the SDT contends that the description of incorrect operations in the proposed Requirement R6 and its Rationale, provide a satisfactory alternative to a formal NERC Glossary definition.

What constitutes functional modification of a RAS? (Davis – maybe include examples of what is and what isn't)

Any modification to RAS hardware beyond the substitution of components that merely preserve the original functionality is a functional change. Any change in RAS logic, RAS relay settings, RAS control settings, or any other modification that affects overall RAS functionality, timing, or redundancy level as documented in the original submission for review are functional changes. RAS modifications identified by a Corrective Action Plan developed pursuant to R5 or R7 beyond the substitution of components that merely preserve the original functionality is a functional change.

Some examples of functional changes include:

- Changes to inputs, outputs, or internal scheme logic
- Major component changes
- Revision of the existing RAS architecture
- CAP modifications resulting from R5 evaluations or R6 incorrect operation reviews

RAS removal is the extreme form of RAS functional modification. Any RAS proposed for removal needs to be evaluated under the "Transmission Planning Evaluation" section of the Attachment 1 checklist. The focus of the reviews for RAS removals should be on the system performance after scheme removal to show that the contingencies that the RAS was designed to mitigate no longer result in the system performance issues that the scheme was intended to mitigate. However, reviews of the sections on the Implementation Design and Operational Data are not really relevant for RAS removals, so are not necessary.

How is the RAS-entity identified, what are the RAS-entity's responsibilities, and what are the responsibilities of other owners of RAS components or Facilities who are not the RAS-entity? (Gene)

How is the RAS-entity identified, what are the RAS-entity's responsibilities, and what are the responsibilities of other owners of RAS components or Facilities who are not the RAS-entity?

The RAS-entity is a NERC functional model entity that owns all or a significant part of the RAS components or other Facilities controlled by the RAS. The RAS-entity will include one of the following:

- Transmission Owner
- Generator Owner
- Distribution Provider

When all RAS components and Facilities controlled by the RAS have a single owner, the RAS-entity is that owner. When the components that make up a RAS and/or RAS-controlled Facilities have more than one owner, the multiple owners may designate a single entity as the RAS-entity. Most often the owner of the RAS controller (when there is one) will be the RAS-entity. However, the various owners may designate some other entity with an ownership interest in the RAS as the RAS-entity.

The RAS-entity has the responsibility to prepare the material identified in Attachment 1 for presentation to the RC, which is the request to approve a new or modified RAS. The RAS-entity will be the primary information conduit for other owners of RAS components and RAS-controlled Facilities during the RAS review process, though other owners may also participate in the RAS review process.

Generator Operators or Transmission Operators of Facilities or components of a RAS have the responsibility to keep all other Operators with a reliability need regarding a RAS informed of any functional modifications made to their individual Facilities or RAS components. This is a form of coordination per PRC-001_R2. While Transmission Owners and Generator Owners do not have direct responsibility under PRC-001, they do have the business interest (and incentive) to approve and finance any appropriate RAS modifications to keep their RAS in compliance with applicable reliability standards.

What is meant by "single RAS component failure" and "redundancy" in this standard? (Gene and Al E.)

The philosophy of the phrase regarding System performance while a RAS experiences a "single component failure" from PRC-012-0 is carried over in to this standard. This phrase is often shortened to "redundancy," but in the context of this discussion, these terms are used interchangeably.

> PRC-012-0 R1.3
> Requirements to demonstrate that the SPS [RAS] shall be designed so that a single SPS [RAS] component failure, when the SPS [RAS] was intended to operate, does not prevent the interconnected transmission system from meeting the performance requirement defined in Reliability Standards TPL-001-0, TPL-002-0, and TPL-003-0.

The critical part of PRC-012 R1.3 is that a RAS "shall be designed so that a "single [RAS] component failure. . . does not prevent the interconnected transmission system from meeting the performance requirements defined in Reliability Standards. . . ." This language certainly covers RAS measuring devices, controls, communications and devices through which RAS action is accomplished.

The NERC SPS white paper suggests that the following RAS components should be covered by the single component failure requirement:

- Any single ac current source and/or related input to the RAS. Separate secondary windings of a free-standing current transformer (CT) or multiple CTs on a common bushing should be considered an acceptable level of redundancy.
- Any single ac voltage source and/or related input to the RAS. Separate secondary windings of a common capacitance coupled voltage transformer (CCVT), voltage transformer (VT), or similar device should be considered an acceptable level of redundancy.
- Any single device used to measure electrical quantities used by the RAS.
- Any single communication channel and/or any single piece of related communication equipment used by the RAS.
- Any single computer or programmable logic device used to analyze information and provide RAS operational output.
- Any single element of the dc control circuitry that is used for the RAS, including breaker closing circuits.
- Any single auxiliary relay or auxiliary device used by the RAS.
- Any single breaker trip coil for any breaker operated by the RAS.
- Any single station battery or single charger, or other single dc source, where central monitoring is not provided for both low voltage and battery open conditions.

This list is consistent with the RAS "redundancy" practices presently accepted by most Regions. For its Type I and Type II schemes, NPCC uses a more extensive list which also includes restrictions, for example, on how control cables may be routed and forbids RAS components from separate (redundant) schemes from sharing control panels. The above "white paper" list is the acceptable minimum redundancy requirement under the terms of this standard.

Duplication of the listed components is a way to achieve redundancy and meet the "single component failure" requirement. For schemes performing distributed actions (e.g. load shedding or generation rejection at multiple locations), over-arming (providing extra corrective action to cover failure to operate of one critical component) can also be an effective option, as long as it does not compromise the performance of the system.

Breaker Failure and Single Component Failure (Gene)

Does the "single component failure" language also cover failure of any System component or Facility that the RAS uses to achieve its intended system impact? This is the interpretation of at least the NPCC and WECC Regions under the existing PRC-012-0, where the emphasis is on "meeting the performance requirements" of the TPL standards.

For example, these Regions apply the philosophy for the failure of a circuit breaker to operate (trip or close), regardless of the number of trip coils, if the operation of the breaker is required to achieve the System performance of the TPL requirements.

The following is from NPCC Regional Reliability Reference Directory # 7 Special Protection Systems (Dec 2013):

> 5.14 Provision for Breaker Failure Criteria
> Type I SPS shall include breaker failure protection for each circuit breaker whose operation is critical to the adequacy of the action taken by the SPS with due regard to the power system conditions this SPS is required to detect. The following are options for breaker failure protection.
>
> 5.15.1 A design which recognizes that the breaker has not achieved or will not achieve the intended function required by the SPS and which takes independent action to achieve that function. This provision needs not be duplicated and can be combined with conventional breaker failure schemes if appropriate.
>
> 5.15.2 Over-arming the SPS such that adequate action is taken even if a single breaker fails.
>
> 5.15.3 The redundancy afforded by actions taken by other independent schemes or devices.

The WECC Remedial Action Scheme Design Guide (2007) uses similar language:

> Failure of a circuit breaker to trip when called upon to trip by the RAS, even when equipped with dual trip coils, is considered a credible failure. Following are some common and acceptable methods to remediate such a failure:
>
> - Over-operate RAS action, e.g. trip extra generation equivalent to the largest generator or generation site which may fail to trip.
> - Initiate breaker failure protection. Breaker failure action usually operates additional breakers to isolate the stuck breaker while still performing the RAS action. Any additional tripping should not exacerbate the original power system problem that the RAS is designed to solve (e.g. avoid tripping additional lines. Refer to the System Performance summary at Table 1 of NERC Standard TPL-001-0 through TPL-004-0 and the WECC MORC.) The breaker failure scheme can also add significantly to the time for a RAS to operate, which may not be acceptable for a high speed transient stability RAS.

The scheme designer is not limited to these methods to address failure of a breaker to trip. However, it should be shown that failure of a breaker to trip (or close) will still result in acceptable system performance.

Furthermore, the failure of a circuit breaker to operate to accomplish its RAS function is not a recognized contingency under the TPL-001-4 standard, so is not counted as the "next" contingency for TPL compliance purposes. The closest contingency category is from Table 1, Category P5,

Category:	Multiple Contingency (Fault plus relay failure to operate)
Initial Condition:	Normal System:
Event	Delayed Fault Clearing due to the failure of a non-redundant relay protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit

3. Transformer
4. Shunt Device
5. Bus Section

Fault Type: SLG

The original contingency that initiates RAS action may well be a SLG fault, but the "second" event directly involving the RAS in this discussion is a failure of a breaker to operate, not "a non-redundant relay protecting the faulted Element" and further identified in a footnote by specified function numbers: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94). The "RAS" event may involve switching of any of the listed Elements, but the RAS would be attempting to accomplish its intended mitigation, not clearing a fault on that Element.

Response based RAS (those that take continuous action until a monitored system quantity recovers) typically do not require breaker failure protection initiation, since failure of any one action to take place will simply mean that the next action on the list will take place and the performance violation will still be mitigated, albeit one time step later. When studying the performance of a response based RAS, system planners will have to assume that the actual operating time of the RAS is one time step longer than designed.

Event based RAS which result in the closing of breakers (typically reactive insertion) must over-operate. Circuit breakers typically have only one close coil and there is no equivalent of breaker failure protection for closing actions. Therefore, when studying the performance of the RAS, the system planner must ensure that the RAS meets performance requirements for all contingencies, even if one breaker fails to close.

Event based RAS which result in the tripping of breakers will by default include the initiation of breaker failure protection. When studying the performance of the RAS, the system planner must ensure that the RAS meets System performance requirements, even if one breaker fails to trip. If the system topology is such that operation of breaker failure protection during a RAS event would exacerbate the performance violation, the system planner must then redefine their functional requirements for the RAS to state that breaker failure protection initiation must not be applied on that breaker, and ensure that the performance of the RAS is acceptable, if that breaker fails to trip, through other mitigating action.

In certain system topologies, and for certain RAS actions, the need to meet performance requirements in the event of a single breaker failure can be achieved by tripping extra breakers as part of the initial RAS action. For example, tripping of the HV and LV breakers of a transformer will interrupt power transfer through the transformer even if one breaker fails to trip. Similarly, tripping both ends of a line will also reliably interrupt power flow through the line, as long as the system meets performance requirements with the line left energized from one bus.

Implementation Plan for Remedial Action Schemes

Project 2010-05.3 Phase 3 of Protection Systems: Remedial Action Schemes (RAS)

Background

In early 2011, NERC divided Project 2010-05: Protection Systems into three phases. Phase 1 addressed the Misoperations of Protection Systems and was adopted by the NERC Board of Trustees on August 14, 2014.

Phase 2 revised the definition of Remedial Action Scheme (RAS). A key element for the reliability of the Bulk-Power System is the correct identification and performance of Special Protection Systems (SPS) and RAS. The defined terms "Special Protection System" and "Remedial Action Scheme" are currently used interchangeably throughout the NERC Regions and in various Reliability Standards. To ensure consistent classification of systems that are RAS and application of Reliability Standards referencing the defined term, on February 3, 2015, NERC filed a petition with FERC, proposing revisions to the existing definition of RAS and corresponding changes in several Reliability Standards. NERC's goal is to gradually modify all of the NERC Reliability Standards to incorporate the use of only a single term Remedial Action Scheme and eliminate the use of the term Special Protection Systems.

Phase 3 of this Project is intended to address all aspects of RAS and SPS contained in the RAS/SPS-related Reliability Standards and regional practices. The existing regional practices lack the specificity necessary for consistent identification and classification of protection schemes as SPS or RAS across the ERO Enterprise. Therefore, Phase 3 of the Project[1] is intended to develop an uniform standard to address all aspects of SPS and RAS, including planning, coordination and design, analysis of operations, and testing and maintenance of PSP/RAS, among other issues.[2] The Project also addresses in part four recommendations related to identification and coordination of SPS included in the joint FERC-NERC Southwest Power Outage Report.

Requested Approval

- PRC-012-2 – Remedial Action Schemes

[1] There is no FERC directive associated with this Project. However, in FERC Order No. 693 (March 16, 2007), FERC identified PRC-012-0, PRC-013-0, and PRC-014-0 as "fill-in-the-blank" standards and did not approve or remand them. These Reliability Standards are applicable to the Regional Reliability Organizations (RROs), assigning the RROs the responsibility to establish regional procedures and databases, and to assess and document the operation, coordination, and compliance of RAS/SPS. These Reliability Standards are used as a basis for drafting PRC-012-2.

[2] See Standards Authorization Request Form at 2. Available at: http://www.nerc.com/pa/Stand/Prjct201005_2SpclPrtctnSstmPhs2/SPS_SAR_02042014.pdf

Requested Withdrawal of Reliability Standards

- PRC-012-0 - Special Protection System Review Procedure
- PRC-013-0 - Special Protection System Database
- PRC-014-0 - Special Protection System Assessment

Requested Retirement of Reliability Standards

- PRC-015-0 - Special Protection System Data and Documentation
- PRC-016-0.1 - Special Protection System Misoperations

Prerequisite Approvals

- Revised Definition of "Remedial Action Scheme" currently pending FERC review

New or Revisions to Defined Terms in the NERC Glossary

- None

Definition(s) Used in Standard

Applicable Entities

- Reliability Coordinator
- Transmission Planner
- RAS-owner – the Transmission Owner, Generator Owner, or Distribution Provider that owns all or part of a RAS
- RAS-entity – the Transmission Owner, Generator Owner, or Distribution Provider designated to represent all owners of the RAS

Conforming Changes to Other Standards

The existing Reliability Standards proposed for retirement contain references to SPS or RAS or both. The revised Reliability Standards will reflect the use of the single term RAS. The revised Reliability Standards noted above for approval are included in a separate document *Revised Reliability Standards for the Revised Definition of "Remedial Action Scheme."*

Effective Dates for Existing Remedial Action Schemes

The proposed Reliability Standard PRC-012-2, as applied to existing RAS, shall become effective on the later day of 1) the day after the revised definition of Remedial Acton Scheme becomes effective or 2) the first day of the first calendar quarter that is twenty-four (24) months after the date the standard is approved by an applicable governmental authority or as otherwise provided for in a jurisdiction where approval by an applicable governmental authority is required for a standard to go into effect. Where

Commented [MY1]: Al, the current definition of SPS states "Also called Remedial Action Scheme." Do you want to include a change in the definition as well, in case we decide not to request changes to the standards using SPS? I think this was the original plan. We can include a reference " See RAS"

Commented [MY2]: I don't think we have some specific definitions not included in the Glossary.

Commented [MY3]: This is in the event we would like to rework the Standards that reference SPS.

Commented [MY4]: revised definition of "Remedial Action Scheme" shall become effective on the first day of the first calendar quarter that is twelve (12) months after the date that the standards and definition are approved by an applicable governmental authority

I think this gives us 12 months under any circumstance.

approval by an applicable governmental authority is not required, the standard shall become effective on the first day of the first calendar quarter that is twenty-four (24) months after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Implementation Plan for Newly Classified Remedial Action Schemes

The proposed Reliability Standard PRC-012-2, as applied to newly classified RAS, shall become effective on the later day of 1) the first day of the first calendar quarter that is twelve (12) months after the effective date of the revised definition of Remedial Acton Scheme or 2) the first day of the first calendar quarter that is twenty four (24) months after the date the standard is approved by an applicable governmental authority or as otherwise provided for in a jurisdiction where approval by an applicable governmental authority is required for a standard to go into effect. Where approval by an applicable governmental authority is not required, the standard shall become effective on the first day of the first calendar quarter that is twenty four (24) months after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Commented [MY5]: 12+12 should be 24.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Description of Current Draft

Draft 1 of PRC-012-2 corrects the applicability of the fill-in-the-blank standards (PRC-012-1, PRC-013-1, PRC-014-1) by assigning the requirement responsibilities to the specific users, owners, and operators of the Bulk-Power System, and incorporates the reliability objectives of all the RAS/SPS-related standards. This draft of PRC-012-2 contains nine (9) requirements and measures, and the associated rationale boxes and corresponding technical guidelines. There are also three (3) attachments within the draft standard incorporated via references in the requirements. This draft of PRC-012-2 is posted for a 45-day initial formal comment period and 10-day ballot.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	February 12, 2014
SAR posted for comment	February 18, 2014
Standards Committee approved the SAR	June 10, 2014

Anticipated Actions	Date
Draft 1 of PRC-012-2 posted for informal comment	April 30 – May 20, 2015
45-day formal comment period with ballot	July 2015
10-day final ballot	October 2015
NERC Board (Board) adoption	November 2015

When this standard receives Board adoption, the rationale boxes will be moved to the Supplemental Material Section of the standard.

A. Introduction

1. **Title:** Remedial Action Schemes
2. **Number:** PRC-012-2
3. **Purpose:** To ensure that Remedial Action Schemes (RAS) do not introduce unintentional or unacceptable reliability risks to the Bulk Electric System (BES).
4. **Applicability:**
   - **4.1. Functional Entities:**
     - **4.1.1.** Reliability Coordinator
     - **4.1.2.** Transmission Planner
     - **4.1.3.** RAS-owner – the Transmission Owner, Generator Owner, or Distribution Provider that owns all or part of a RAS
     - **4.1.4.** RAS-entity – the Transmission Owner, Generator Owner, or Distribution Provider designated to represent all owners of the RAS
   - **4.2. Facilities:**
     - **4.2.1.** Remedial Action Schemes (RAS)
5. **Effective Date:** See Implementation Plan for Project 2010-05.3 PRC-012-2

B. Requirements and Measures

Rationale for Requirement R1: Each Remedial Action Scheme (RAS) is unique and its action(s) can have a significant impact on the reliability and integrity of the Bulk Electric System (BES); therefore, a review of a proposed new RAS or an existing RAS proposed for functional modification or retirement (removal from service) must be completed prior to implementation. A functional modification is any modification to a RAS beyond the replacement of components that preserves the original functionality.To facilitate a review that promotes reliability, the RAS-entity must provide the reviewer with sufficient details of the RAS design, function, and operation. This data and supporting documentation are identified in Attachment 1 of this standard, and Requirement R1 mandates the RAS-entity provide them to the reviewing Reliability Coordinator (RC). A specific time period for the RAS-entity to provide Attachment 1 to the reviewing RC is not necessary because an expeditious submittal is in the self-interest of the RAS-owner(s) to effect a timely implementation. The RC responsible for the review will be the RC that coordinates the area where the RAS is located. In cases where a RAS crosses multiple RC Area boundaries, each affected RC would be responsible for conducting either individual reviews or a coordinated review.

R1. Prior to placing a new or functionally modified RAS in-service or retiring an existing RAS, each RAS-entity shall submit the information identified in Attachment 1 to the reviewing Reliability Coordinator(s) to enable RAS review per Requirement R2. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M1. Acceptable evidence is a copy of the Attachment 1 documentation and the dated communications with the reviewing Reliability Coordinator(s) in accordance with Requirement R1.

Rationale for Requirement R2: Requirement R2 mandates that the Reliability Coordinator (RC) perform a review of a proposed new RAS or an existing RAS proposed for functional modification or retirement (removal from service) in its RC area.

The RC is the functional entity best-suited to perform the RAS reviews because it has a wide-area perspective of reliability that includes awareness of reliability issues in its neighboring RC Areas. This wide-area purview provides continuity in the review process and better facilitates the coordination of interactions among separate RAS as well as the coordination of interactions among RAS and other protection and control systems. The selection of the RC also minimizes the possibility of a “conflict of interest” that could exist because of business relationships among the RAS-Entity, Planning Coordinator (PC), Transmission Planner (TP), or other entity that are often involved in the planning or implementation of a RAS. The PC is included as part of the review team, though without decision authority, to make sure that Planning horizon concerns are adequately addressed. The RC may request aid in RAS reviews from other parties such as the Planning Coordinator or regional technical groups; however, the RC will retain the responsibility of compliance with this requirement.

Attachment 2 of this standard is a checklist provided to the RC to assist in identifying important design and implementation aspects of RAS, and in facilitating consistent reviews for each RAS submitted. The time frame of four full calendar months is consistent with current utility and regional practice; however, flexibility is provided by allowing the parties to negotiate a different schedule for the review.

Note: An RC may need to include this task in its reliability plan(s) for the Region(s) in which it is located.

R2. For each RAS submitted pursuant to Requirement R1, each reviewing Reliability Coordinator shall, within four full calendar months of receipt of Attachment 1 materials, or on a mutually agreed upon schedule, perform a review of the RAS in accordance with Attachment 2, and provide written feedback to the RAS-entity. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M2. Acceptable evidence may include, but is not limited to, date-stamped reports, or other documentation detailing the RAS review, and the dated communications with the RAS-entity in accordance with Requirement R2.

Rationale for Requirement R3: Requirement R3 mandates the RAS-entity address all issues identified by the Reliability Coordinator (RC) during the RAS review, and obtain approval from the RC that the RAS implementation can proceed. This interaction promotes reliability by minimizing the introduction of inadvertent actions (risks) to the BES. A specific time period for the RAS-entity to respond to the RC's review is not necessary because an expeditious response is in the self-interest of the RAS-owner(s) to effect a timely implementation. The review by the RC is intended to identify reliability issues that must be resolved before the RAS can be put in service. The reliability issues could involve dependability, security, or both. A more detailed explanation of dependability and security is included in the Supplemental Materials section of the standard.

R3. Following the review performed pursuant to Requirement R2, the RAS-entity shall address each identified issue and obtain approval from each reviewing Reliability Coordinator, prior to placing a new or functionally modified RAS in-service or retiring an existing RAS. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M3. Acceptable evidence may include, but is not limited to, date-stamped documentation and date-stamped communications with the reviewing Reliability Coordinator in accordance with Requirement R3.

Rationale for Requirement R4: Requirement R4 mandates that a evaluation of each RAS be performed at least once every 60 full calendar months. The purpose of periodic RAS evaluation is to verify the continued effectiveness and coordination of the RAS, as well as BES performance following an inadvertent RAS operation. This periodic evaluation is needed due to possible changes in system topology and operating conditions that may

have occurred since the previous RAS evaluation (or initial review) was completed. Sixty (60) full calendar months was selected as the maximum time frame for the evaluation based on the time frames for similar requirements in Reliability Standards PRC-006-1, PRC-010-1, and PRC-014-1. The RAS evaluation can be performed sooner if it is determined that material changes to system topology or system operating conditions that could potentially impact the effectiveness or coordination of the RAS have occurred since the previous RAS evaluation or will occur before the next scheduled evaluation. The periodic RAS evaluation will typically lead to one of the following outcomes: 1) affirmation that the existing RAS is adequate; 2) identification of changes needed to the existing RAS; or, 3) justification for RAS retirement.

The items required to be addressed in the evaluations (Parts 4.1, 4.2, 4.3) are planning analyses which involve modeling of the interconnected transmission system; consequently, the Transmission Planner (TP) is the functional entity best qualified to perform the analyses. To promote reliability, the TP is required to provide the RAS-owner(s) and the Reliability Coordinator(s) with the results of each evaluation.

R4. Each Transmission Planner shall perform an evaluation of each RAS within its planning area at least once every 60 full calendar months and provide the RAS-owner(s) and the reviewing Reliability Coordinator(s) the results including any identified deficiencies. Each evaluation shall determine whether: *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. The RAS mitigates the System condition(s) or contingency(ies) for which it was designed.

4.2. The RAS avoids adverse interactions with other RAS, and protection and control systems.

4.3. The possible inadvertent operation of the RAS resulting from any single RAS component inadvertent operation satisfies all of the following:

4.3.1. The BES shall remain stable.

4.3.2. Cascading shall not occur.

4.3.3. Applicable Facility Ratings shall not be excedded.

4.3.4. BES voltages shall be within post-Contingency voltage limits and post-Contingency voltage deviation limits as established by the Transmission Planner and the Planning Coordinator.

4.3.5. Transient voltage responses shall be within acceptable limits as established by the Transmission Planner and the Planning Coordinator.

4.4. A single component failure in the RAS, when the RAS is intended to operate, does not prevent the BES from meeting the same performance requirements (defined in Reliability Standard TPL-001-4 or its successor) as those required for the events and conditions for which the RAS was designed.

M4. Acceptable evidence may include, but is not limited to, date-stamped reports or other documentation of the analyses comprising the evaluation(s) of each RAS and date-stamped communications with the RAS-owner(s) and the Reliability Coordinator(s) in accordance with Requirement R4.

Rationale for Requirement R5: The correct operation of a RAS is important to maintaining the reliability and integrity of the Bulk Electric System (BES). Any incorrect operation of a RAS indicates the RAS effectiveness and/or coordination has been compromised. Therefore, all operations of a RAS and failures of a RAS to operate when expected must be analyzed to verify that the RAS performance was consistent with its intended functionality and design. The 120 calendar day time frame aligns with the time frame established in Requirement R1 from PRC-004-4 regarding the investigation of a Protection System Misoperation.

The RAS-owner(s) will need to collaborate with its associated Transmission Planner(s) to analyze the RAS performance and System response (Parts 5.1, 5.2, 5.3, 5.4). To promote reliability, the RAS-owner(s) is required to provide the results of performance analyses to its Reliability Coordinator(s).

R5. Each RAS-owner(s) and its associated Transmission Planner(s) shall, within 120-calendar days of a RAS operation or failure of a RAS to operate when expected, analyze the RAS performance and provide the results of the analysis, including any identified deficiencies, to its reviewing Reliability Coordinator(s). The analysis shall determine whether the: *[Violation Risk Factor:Medium] [Time Horizon:Operations Planning]*

5.1. System events and/or conditions appropriately triggered the RAS.

5.2. RAS responded as designed.

5.3. RAS was effective in mitigating BES performance issues it was designed to address.

5.4. RAS operation resulted in any unintended or adverse power System response.

M5. Acceptable evidence may include, but is not limited to, date-stamped documentation detailing the RAS operational performance analysis in accordance with Requirement R5.

Rationale for Requirement R6: Deficiencies identified either in the periodic RAS evaluation conducted by the Transmission Planner in Requirement R4, or in the analysis conducted by the RAS-owner(s) pursuant to Requirement R5 are likely to pose a reliability risk to the BES due to the impact of either a RAS operation or incorrect operation. To avoid this reliability risk, Requirement R6 mandates that the RAS-owner(s) develop a Corrective Action Plan that establishes the mitigation methods and timetable to address the deficiency. If the Corrective Action Plan requires that a functional change be made to

a RAS, the RAS-owner(s) will need to submit information identified in Attachment 1 to the RC(s) for review prior to placing RAS modifications in service per Requirement 1.

Depending on the complexity of the issues, development of a CAP may require study, engineering, or consulting work. A timeframe of six full calendar months is specified to allow enough time for RAS-owner collaboration on the CAP development, while ensuring that deficiencies are addressed in a reasonabe time. A RAS deficiency may require the Reliability Coordinator or Transmission Operator to impose operating restrictions so the system can operate in a reliable way until the RAS deficiency is resolved. Such operating restrictions will incent the RAS-owner to resolve the issue as quickly as possible.

R6. Within six full calendar months of being notified of a deficiency in its RAS, based on the evaluation performed pursuant to Requirement R4, or of identifying a performance deficiency in its RAS based on the analysis performed pursuant to Requirement R5, each RAS-owner shall participate in developing a Corrective Action Plan and submitting it to its reviewing Reliability Coordinator. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning, Long-term Planning]*

M6. Acceptable evidence may include, but is not limited to, a date-stamped Corrective Action Plan and date-stamped communications with each reviewing Reliability Coordinator in accordance with Requirement R6.

Rationale for Requirement R7: Requirement R7 mandates the RAS-owner(s) implement a Corrective Action Plan submitted to address any identified deficiency(ies) found in conjunction with the periodic evaluation pursuant to Requirement R4, and any identified incorrect operation found by the analysis of an actual RAS operation pursuant to Requirement R5. Since the NERC Glossary of Terms defines a Corrective Action Plan (CAP) as "A list of actions and an associated timetable for implementation to remedy a specific problem", the implemention of a properly developed CAP submitted pursuant to Requirement R6 ensures that any identified deficiency(ies) or incorrect operation(s) are addressed by following a documented schedule of actions.

R7. For each CAP submitted pursuant to Requirement R6, each RAS-owner shall implement the CAP and update each CAP if actions or timetables change, until completed. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning, Long-term Planning]*

M7. Acceptable evidence may include, but is not limited to, dated documentation (electronic or hardcopy format) such as Corrective Action Plans, project or work management program records, settings sheets, work orders, and maintenance records that document the implementation of a CAP in accordance with Requirement R7.

Rationale for Requirement R8: Due to the wide variety of RAS designs and implementations, and the potential for impacting BES reliability, it is important that

periodic functional testing of RAS is performed. A functional test provides an overall confirmation of the RAS's ability to operate as designed and verifies the proper operation of the non-Protection System (control) components of a RAS that are not addressed in PRC-005. Protection System components that are part of a RAS are maintained in accordance with PRC-005. The component testing focus of PRC-005 is fundamentally different from functional testing required here. Functional testing verifies RAS performance rather than straightforward component health verification. The six calendar year interval was selected because it coincides with the maintenance intervals of various Protection System and Automatic Reclosing components established in PRC-005-3, thus providing entities the opportunity to align maintenance of Protection System Components with functional RAS testing, if scheduled outages are necessary. Extending to longer intervals could expose a latent failure, creating a BES reliability risk. The RAS-owner is in the best position to determine the testing procedure and schedule due to its overall knowledge of the RAS design, installation, and expected operation. Periodic functional testing promotes the identification of changes in System infrastructure that could have introduced latent failures into the RAS. Functional testing may be accomplished with end-to-end testing or a segmented approach. Each segment of a RAS should be tested but overlapping segments can be tested individually negating the need for complex maintenance schedules and outages. A correct operation of a RAS qualifies as a functional test as long as all segments operate. Should an event operate less than the full RAS, the segments without an operation will need a functional test within the 6 year interval to be compliant with this Requirement.

R8. At least once every six calendar years, each RAS-owner shall perform a functional test of each RAS to verify the overall RAS performance and the proper operation of non-Protection System components. *[Violation Risk Factor: High] [Time Horizon:Long-term Planning]*

M8. Acceptable evidence may include, but is not limited to, date-stamped documentation of the functional testing.

Rationale for Requirement R9: The RAS database is a comprehensive record of all RAS existing in a Reliability Coordinator's area. The database enables the RC to provide other entities the ability to obtain high level information on existing RAS that can potentially impact the entities' operational and/or planning activities. Attachment 3 lists the minimum information required for the RAS database, which includes a summary of the RAS initiating conditions, corrective actions, and System issues being mitigated. This information allows an entity to evaluate the reliability need for requesting more detailed information from the RAS-entity identified in the database contact information. The Reliability Coordinator (RC) is the appropriate entity to maintain the database because the RC receives the required database information when a new or modified RAS is submitted for review.

R9. Each Reliability Coordinator shall update a RAS database containing the information in Attachment 3 at least once each calendar year. *[Violation Risk Factor: Lower] [Time Horizon: Operations Planning]*

M9. Acceptable evidence may include, but is not limited to, date-stamped spreadsheets, database reports, or other documentation demonstrating a RAS database was maintained in accordance with Requirement R9.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:
As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention:
The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

> The applicable entity shall keep data or evidence to show compliance with requirements **(DELETE GREEN TEXT PRIOR TO PUBLISHING) Add requirements as appropriate for this standard. This section is only for those requirements that do not have the default data retention.** since the last audit.

1.3. Compliance Monitoring and Enforcement Program
As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.				The RAS-entity failed to submit the information identified in Attachment 1 to the reviewing Reliability Coordinator(s) prior to placing a new or functionally modified RAS in-service or retiring an existing RAS in accordance with Requirement R1.
R2.			The reviewing Reliability Coordinator failed to complete the review and provide the written feedback within four full calendar months or the mutually agreed upon schedule in accordance with Requirement R2.	The reviewing Reliability Coordinator failed to perform the review in accordance with Requirement R2. OR The reviewing Reliability Coordinator failed to provide the written feedback in accordance with Requirement R2.
R3.				The RAS-entity failed to obtain approval from each reviewing Reliability Coordinator prior to placing

				a new or functionally modified RAS in-service or retiring an existing RAS in accordance with Requirement R3.
R4.	The Transmission Planner performed the evaluation in accordance with Requirement R4, in greater than 60 full calendar months but less than 61 full calendar months.	The Transmission Planner performed the evaluation in accordance with Requirement R4, in greater than 61 full calendar months but less than 62 full calendar months.	The Transmission Planner performed the evaluation in accordance with Requirement R4, in greater than 62 full calendar months but less than 63 full calendar months. OR The Transmission Planner performed the evaluation in accordance with Requirement R4 but failed to evaluate one of the Parts.	The Transmission Planner performed the evaluation in accordance with Requirement R4, in greater than 63 full calendar months or failed to provide the evaluation at all. OR The Transmission Planner performed the evaluation in accordance with Requirement R4 but failed to evaluate two or more of the Parts. OR The Transmission Planner performed the evaluation in accordance with Requirement R4 but failed to provide the results to the RAS-owner(s) and the reviewing Reliability Coordinator(s).

R5.	The responsible entity performed the analysis in greater than 120 calendar days but no more than 130 calendar days in accordance with Requirement R5.	The responsible entity performed the analysis in greater than 130 calendar days but no more than 140 calendar days in accordance with Requirement R5.	The responsible entity performed the analysis in greater than 140 calendar days but no more than 150 calendar days in accordance with Requirement R5. OR The responsible entity performed the analysis in accordance with Requirement R5 but failed to address one of the Parts.	The responsible entity performed the analysis in greater than 150 calendar days. OR The responsible entity failed to provide the analysis in accordance with Requirement R5. OR The responsible entity performed the analysis in accordance with Requirement R5 but failed to address two or more of the Parts. Attachment 1
Supporting Documentation for RAS Review

The following checklist identifies important RAS information for each new or functionally modified[1] RAS that the RAS-entity shall document and provide to the Reliability Coordinator for review pursuant to Requirement R1. If an item on this list does not apply to a specific RAS, a response of NA or Not Applicable for that item is appropriate. When a RAS has been previously reviewed, only the proposed modifications to that RAS require review; however, the RAS entity must provide a summary of the previously approved functionality. The RC may request additional information on any reliability issue related to the RAS. Additional entities (without decision authority) may be part of the RAS review process at the request of the RC.

I. General

1. Information such as maps, one-line drawings, substation and schematic drawings that identify the physical and electrical location of the RAS and related facilities.

2. Functionality of new RAS or proposed functional modifications to existing RAS and documentation of the pre- and post-modified functionality of the RAS.

3. The Corrective Action Plan (CAP) if RAS modifications are proposed in a CAP.
   [Reference NERC Reliability Standard PRC-012, Requirements R5 and R7]

4. Initial data to populate the RAS database:
   1. RAS name
   2. RAS-entity and contact information
   3. Expected or actual in-service date; most recent (Requirement R3) RC-approval date; most recent 60 full calendar month (Requirement R4) evaluation date; and, date of retirement, if applicable
   4. System performance issue or reason for installing the RAS (*e.g.*, thermal overload, angular instability, poor oscillation damping, voltage instability, under-/over-voltage, slow voltage recovery)
   5. Description of the contingencies or System conditions for which the RAS was designed (initiating conditions)
   6. Corrective action taken by the RAS
   7. Any additional explanation relevant to high level understanding of the RAS

II. Functional Description and Transmission Planning Information

1. Contingencies and system conditions that the RAS is intended to remedy.
   [Reference NERC Reliability Standards PRC-012, R1.2 and PRC-013, R1.1]

[1] Functionally Modified:
Any modification to a RAS beyond the replacement of components that preserve the original functionality is a functional modification.

2. The actions to be taken by the RAS in response to disturbance conditions.
   [Reference NERC Reliability Standards PRC-012, R1.2 and PRC-013, R1.2]

3. A summary of technical studies, if applicable, demonstrating that the proposed RAS actions satisfy System performance objectives for the scope of System events and conditions that the RAS is intended to remedy. The technical studies summary shall also include information such as the study year(s), system conditions, and contingencies analyzed on which the RAS design is based, and when those technical studies were performed.
   [Reference NERC Reliability Standard PRC-014, R3.2]

4. Information regarding any future system plans that will impact the RAS.
   [Reference NERC Reliability Standard PRC-014, R3.2]

5. Documentation showing that the possible inadvertent operation of the RAS resulting from any single RAS component inadvertent operation satisfies all of the following:
   - The BES shall remain stable.
   - Cascading shall not occur.
   - Applicable Facility Ratings shall not be exceeded.
   - BES voltages shall be within post-Contingency voltage limits and post-Contingency voltage deviation limits as established by the Transmission Planner and the Planning Coordinator.
   - Transient voltage responses shall be within acceptable limits as established by the Transmission Planner and the Planning Coordinator

   [Reference NERC Reliability Standard PRC-012, R1.4]
6. An evaluation indicating that the RAS settings and operation avoid adverse interactions with other RAS, and protection and control systems.
   [Reference NERC Reliability Standards PRC-012, R1.5 and PRC-014, R3.4]

7. Identification of other affected RCs.

III. Implementation

1. Documentation describing the equipment used for detection, telecommunications, transfer trip, logic processing, and monitoring, whichever are applicable.

2. Information on detection logic and settings/parameters that control the operation of the RAS. [Reference NERC Reliability Standards PRC-012, R1.2 and PRC-013, R1.3]

3. Documentation showing that any multifunction device used to perform RAS function(s), in addition to other functions such as protective relaying or SCADA, does not compromise the reliability of the RAS when the device is not in service or is being maintained.

4. Documentation showing that a single component failure in the RAS, when the RAS is intended to operate, does not prevent the BES from meeting the same performance requirements (defined in Reliability Standard TPL-001-4 or its successor) as those required for the events and conditions for which the RAS was designed. The documentation should describe or illustrate how the implementation design achieves this objective.
   [Reference NERC Reliability Standard PRC-012, R1.3]

5. Documentation describing the functional testing process.

IV. RAS Retirement

The following checklist identifies important RAS information for each existing RAS to be retired that the RAS-entity shall document and provide to the Reliability Coordinator for review pursuant to Requirement R1.

1. Information necessary to ensure that the Reliability Coordinator is able to understand the physical and electrical location of the RAS and related facilities.
2. A summary of applicable technical studies and technical justifications upon which the decision to retire the RAS is based.
3. Anticipated date of RAS retirement.

Commented [GH1]: Do we need this bullet? Doesn't hurt.

Commented [GH2]: 2 alternate wording options

Attachment 2
Reliability Coordinator RAS Review Checklist

The following checklist identifies reliability-related considerations for the Reliability Coordinator (RC) to review and verify pursuant to Requirement R2 for each new or functionally modified[2] RAS. The RC review is not limited to the checklist items and the RC may request additional information on any reliability issue related to the RAS.

I. DESIGN

1. The RAS actions satisfy performance objectives for the scope of events and conditions that the RAS is intended to mitigate.

2. The RAS arming conditions, if applicable, are appropriate to its System performance objectives.

3. The RAS avoids adverse interactions with other RAS, Protection Systems, control systems, and Operating Procedures.

4. The effects of RAS incorrect operation, including inadvertent operation and failure to operate (if non-operation for RAS single component failure is acceptable), have been identified.

5. The Documentation showing that the possible inadvertent operation of the RAS resulting from any single RAS component inadvertent operation satisfies all of the following:
   - The BES shall remain stable.
   - Cascading shall not occur.
   - Applicable Facility Ratings shall not be exceeded.
   - BES voltages shall be within post-Contingency voltage limits and post-Contingency voltage deviation limits as established by the Transmission Planner and the Planning Coordinator.
   - Transient voltage responses shall be within acceptable limits as established by the Transmission Planner and the Planning Coordinator

6. The effects of future BES modifications on the design and operation of the RAS, where applicable, have been identified.

II. IMPLEMENTATION

1. The implementation of RAS logic appropriately correlates desired actions (outputs) with events and conditions (inputs).

2. The timing of RAS action(s) is appropriate to its BES performance objectives.

3. A single component failure in a RAS does not prevent the BES from meeting the same

[2] Functionally Modified:
Any modification to a RAS beyond the replacement of components that preserve the original functionality is a functional modification.

performance requirements as those required for the events and conditions for which the RAS was designed.

4. The RAS design facilitates periodic testing and maintenance.
5. The mechanism or procedure by which the RAS is armed is clearly described, and is appropriate for reliable arming and operation of the RAS for the conditions and events for which it is designed to operate.
6. RAS automatic arming, if applicable, has the same degree of redundancy as the RAS itself.

III. RAS Retirement

RAS retirement reviews should assure that there is adequate Planning justification for why a RAS is no longer needed.

Attachment 3
Database Information

1. RAS name.
2. RAS-entity and contact information.
3. Expected or actual in-service date; most recent (Requirement R3) RC-approval date; most recent 60 full calendar-month (Requirement R4) evaluation date; and, date of retirement, if applicable.
4. System performance issue or reason for installing the RAS (*e.g.*, thermal overload, angular instability, poor oscillation damping, voltage instability, under-/over-voltage, slow voltage recovery).
5. Description of the contingencies or System conditions for which the RAS was designed (initiating conditions).
6. Corrective action taken by the RAS.
7. Any additional explanation relevant to high level understanding of the RAS.

Supplemental Material

Technical Justifications for Requirements

Requirement R1:

Each Remedial Action Scheme (RAS) is unique and its action(s) can have a significant impact on the reliability and integrity of the Bulk Electric System (BES); therefore, a review of a proposed new RAS or an existing RAS proposed for functional modification or retirement (removal from service) must be completed prior to implementation. A functional modification is any modification to a RAS beyond the replacement of components that preserves the original functionality.To facilitate a review that promotes reliability, the RAS-entity must provide the reviewer with sufficient details of the RAS design, function, and operation. This data and supporting documentation are identified in Attachment 1 of this standard, and Requirement R1 mandates the RAS-entity provide them to the reviewing Reliability Coordinator (RC). The RC responsible for the review will be the RC that coordinates the area where the RAS is located. In cases where a RAS crosses multiple RC Area boundaries, each affected RC would be responsible for conducting either individual reviews or a coordinated review.

Requirement R2:

Requirement R2 mandates that the Reliability Coordinator (RC) perform a review of a proposed new RAS or an existing RAS proposed for functional modification or retirement (removal from service) in its RC area.

The RC is the functional entity best-suited to perform the RAS reviews because it has a wide-area perspective of reliability that includes awareness of reliability issues in its neighboring RC Areas. This wide-area purview provides continuity in the review process and better facilitates the coordination of interactions among separate RAS as well as the coordination of interactions among RAS and other protection and control systems. The selection of the RC also minimizes the possibility of a “conflict of interest” that could exist because of business relationships among the RAS-Entity, Planning Coordinator (PC), Transmission Planner (TP), or other entity that could be involved in the planning or implementation of a RAS. The RC may designate a third party to conduct the RAS reviews; however, the RC will retain the responsibility of compliance with this requirement.

Attachment 2 of this standard is a checklist provided to the RC to assist in identifying important design and implementation aspects of RAS, and in facilitating consistent reviews for each RAS submitted. The time frame of four full calendar months is consistent with current utility practice; however, flexibility is provided by allowing the parties to negotiate a different schedule for the review.

Note: An RC may need to include this task in its reliability plan(s) for the Region(s) in which it is located

Requirement R3:

Requirement R3 mandates the RAS-entity address all reliability-related issues identified by the Reliability Coordinator (RC) during the RAS review, and obtain approval from the RC that the RAS implementation can proceed. This interaction promotes reliability by minimizing the introduction of inadvertent actions (risks) to the BES. A specific time period for the RAS-entity

to respond to the RC's review is not necessary because an expeditious response is in the self-interest of the RAS-owner(s) to effect a timely implementation. The review by the RC is intended to identify reliability issues that must be resolved before the RAS can be put in service. The reliability issues could involve dependability, security, or both.

Dependability is a component of reliability and is the measure of a device's certainty to operate when required. Since RAS are usually installed to meet performance requirements of NERC standards, a failure of the RAS to operate when intended would put the System at risk of violating NERC performance standards if the critical contingency(ies) or System conditions occur. This risk is usually mitigated by installing an appropriate level of redundancy as part of the RAS so that it will still accomplish its intended purpose even while experiencing a single component failure.

Security is a component of reliability and is the measure of a device's certainty not to operate falsely. False, or inadvertent operation of a RAS results in taking some programmed action that the RAS would take for a correct operation, but without either the appropriate arming conditions or occurrence of the critical contingency(ies) or System conditions expected to trigger the RAS action. Typically these actions include shedding load or generation or re-configuring the System. This inadvertent action is undesirable in the absence of the critical System conditions and may, on its own, put the System in a less secure state. The standard allows an impact up to the level that would occur for a correct operation. If this risk needs to be further mitigated, voting schemes have been successfully used in the industry for both RAS and Protection systems.

Either type of reliability issue must be resolved before placing the RAS in service to avoid placing the System at unacceptable risk. The RAS-entity (and any other RAS-owner) or the RC may have alternative ideas or methods available to resolve the issue(s). In either case, the concern needs to be resolved in favor of reliability, and the RC has the final decision.

Requirement R4:

Requirement R4 mandates that an evaluation of each RAS be performed at least once every 60 full calendar months. The purpose of periodic RAS evaluation is to verify the continued effectiveness and coordination of the RAS, as well as to verify that BES performance requirements for inadvertent RAS operation and single component failure continue to be satisfied. A periodic evaluation is needed because changes in system topology or operating conditions that have occurred since the previous RAS evaluation (or initial review) was completed may change the effectiveness of a RAS or the the way it interacts with and impacts the BES.

Sixty (60) full calendar months was selected as the maximum time frame for the evaluation based on the time frames for similar requirements in Reliability Standards PRC-006-1, PRC-010-1, and PRC-014-1. The RAS evaluation can be performed sooner if it is determined that material changes to system topology or system operating conditions that could potentially impact the effectiveness or coordination of the RAS have occurred since the previous RAS evaluation or will occur before the next scheduled evaluation. The periodic RAS evaluation will typically lead to

one of the following outcomes: 1) affirmation that the existing RAS is adequate; 2) identification of changes needed to the existing RAS; or, 3) justification for RAS retirement.

The items required to be addressed in the evaluations (Parts 4.1, 4.2, 4.3, 4.4) are planning analyses which involve modeling of the interconnected transmission system to assess BES performance; consequently, the Transmission Planner (TP) is the functional entity best qualified to perform the analyses. To promote reliability, the TP is required to provide the RAS-owner(s) and the Reliability Coordinator(s) with the results of each evaluation.

Requirements for inadvertent RAS operation (4.3) and single component failure (4.4) are reviewed by the RC before a new or modified RAS is placed in service, and are typically satisfied with specific design considerations. Although the scope of the 60 month evaluation does not include a new design review, it is possible that a design which previously satisfied requirements for inadvertent RAS operation and single component failure may fail to do so at a later point in time, and must be evaluated with respect to the current System. For example, System changes could occur impacting the amount of load tripped by a particular RAS output. Inadvertent activation of that output could begin tripping too much load, resulting in violations of Facility Ratings; alternatively, a RAS designed to "over-trip" more load than necessary in order to compensate for single component failure may no longer trip enough load at affected locations, resulting in unacceptable BES performance if one of the loads failed to trip.

Requirement R5:

The correct operation of a RAS is important to maintaining the reliability and integrity of the Bulk Electric System (BES). Any incorrect operation of a RAS indicates the RAS effectiveness and/or coordination has been compromised. Therefore, all operations of a RAS and failures of a RAS to operate when expected must be analyzed to verify that the RAS performance was consistent with its intended functionality and design. The 120 calendar day time frame aligns with the time frame established in Requirement R1 from PRC-004-4 regarding the investigation of a Protection System Misoperation.

The RAS-owner(s) will need to collaborate with its associated Transmission Planner(s) to analyze the RAS performance and System response (Parts 5.1, 5.2, 5.3, 5.4). To promote reliability, the RAS-owner(s) is required to provide the results of performance analyses to its Reliability Coordinator(s).

Requirement R6:

Deficiencies identified either in the periodic RAS evaluation conducted by the Transmission Planner in Requirement R4, or in the analysis conducted by the RAS-owner(s) pursuant to Requirement R5 are likely to pose a reliability risk to the BES due to the impact of either a RAS operation or incorrect operation. To avoid this reliability risk, Requirement R6 mandates that the RAS-owner(s) develop a Corrective Action Plan that establishes the mitigation methods and timetable to address the deficiency. If the Corrective Action Plan requires that a functional change be made to a RAS, the RAS-owner(s) will need to submit information identified in Attachment 1 to the RC(s) for review prior to placing RAS modifications in service per Requirement 1.

Supplemental Material

Depending on the complexity of the issues, development of a CAP may require study, engineering, or consulting work. A timeframe of six full calendar months is specified to allow enough time for RAS-owner collaboration on the CAP development, while ensuring that deficiencies are addressed in a reasonabe time. A RAS deficiency may require the Reliability Coordinator or Transmission Operator to impose operating restrictions so the system can operate in a reliable way until the RAS deficiency is resolved. Such operating restrictions will incent the RAS-owner to resolve the issue as quickly as possible.

A Corrective Action Plan (CAP) documents a RAS performance deficiency, the strategy to correct the deficiency with identified tasks, the responsible party assigned to each task, and the targeted completion date(s).

The following are examples situations of when a CAP is required:

a) A determination after a RAS operation/non-operation investigation that the RAS did not meet performance expectations. The RAS did not operate as designed.
b) Periodic planning assessment reveals RAS changes are necessary to satisfy performance effectiveness or to correct identified coordination issues.
c) Equipment failure detrimentally affects the dependability or security of the RAS.

Requirement R7:

Requirement R7 mandates the RAS-owner(s) implement a Corrective Action Plan submitted to address any identified deficiency(ies) found in conjunction with the periodic evaluation pursuant to Requirement R4, and any identified incorrect operation found by the analysis of an actual RAS operation pursuant to Requirement R5. Since the NERC Glossary of Terms defines a Corrective Action Plan (CAP) as “A list of actions and an associated timetable for implementation to remedy a specific problem”, the implemention of a properly developed CAP submitted pursuant to Requirement R6 ensures that any identified deficiency(ies) or incorrect operation(s) are addressed by following a documented schedule of actions.

Requirement R8:

The reliability objective of Requirement R8 is to test the non-Protection System components of a RAS (controllers such as PLCs) and to verify the overall performance of the scheme through functional testing. Functional tests validate RAS operation by ensuring system states are detected and processed, and that actions taken by the controls are correct and within the expected time frames using the in-service settings and logic. Since functional testing is aimed at overall RAS performance, the SDT chose to address RAS testing in PRC-012-2 rather than include it in the component focused PRC-005 Standard.

Functional testing can be difficult to schedule and perform, but it is critical to ensure the proper functioning of RAS and, therefore, BES reliability. Since the functional test operates the Scheme under controlled conditions with known system states and expected results, testing and result analysis can be performed without impact to the BES. The RAS-owner is in the best position to determine the testing procedure and schedule due to their overall knowledge of the RAS design, installation, and expected operation. Periodic testing provide the RAS owner assurance that latent failures are not present in the RAS design and implementation, and also promotes identification of changes in System infrastructure may have introduced latent failures.

Supplemental Material

The six calendar year interval coincides with the maintenance intervals of various Protection System and Automatic Reclosing components established in PRC-005-3, but is greater than the annual or bi-annual testing used in many Regions. The choice of this interval also considered risks to BES reliability as a latent failure is more likely to cause an incorrect operation the longer it remains undetected.. The SDT suggests that entities design their functional testing program for this Requirement include the Table activities from PRC-005 to avoid duplication for components common to both Standards; functional testing done for PRC-012 R8 could satisfy the Requirements of PRC-005.

Functional testing is not synonymous with end-to-end testing. End-to-end testing is acceptable and may be used, but is not be feasible for many RAS. If end-to-end testing is not possible, a segmented functional testing approach is recommended. The segments can be tested individually negating the need for complex maintenance schedules. In addition, the SDT accepts that actual RAS operation(s) can be used to fulfill the functional testing Requirement. If a RAS does not operate in its entirety during a system event or system conditions do not allow a complete end-to-end system test, the segmented approach can be used to fulfill this Requirement. The goal of a functional test procedure is inclusion of all conditions the RAS uses for detection, arming, operating, and data collection, processing via the logic and infrastructure of a RAS, addressing the system condition(s) for which the RAS is designed. All segments and components of a RAS must be tested or have proven operations within a 6 year interval to demonstrate compliance with the Requirement.

As an example, consider a RAS implemented using one control component not addressed in the Protection System definition but used regularly in RAS: a programmable logic controller (PLC). The PLC does not meet the definition of a Protection System and will have no required maintenance as part of PRC-005-2. In this simplified example, the PLC based RAS is sensing system conditions such as loading and line status from many locations, and implements breaker tripping at multiple locations to alleviate an overload condition. At one of these locations, a line protective relay, included in a RAS-owners PSMP as a Protection System component, is used to operate a breaker upon receipt an operate command from the remote RAS PLC. The relay sends data and receives commands from the RAS PLC over non-Protection System communications infrastructure. A functional test would simulate via external signals to the PLC system conditions requiring an operate command to the protective relay, operating its associated breaker. This action verifies RAS action, verifies PLC control logic, and verifies of RAS communications from PLC to relay. To complete this portion of a functional test, application of external testing signals to the protective relay, verified at the PLC are necessary to confirm full functioning of the RAS zone being tested. As this example RAS is implemented across several locations, the testing described would only constitute one segment of a full RAS functional test. The remaining segments in the RAS design would also require testing.

IEEE C37.233, “IEEE Guide for Power System Protection Testing,” section 8 (particularly 8.3-8.5), provides a very good overview of functional testing. The following opens section 8.3:

> “Proper implementation requires a well-defined and coordinated test plan for performance evaluation of the overall system during agreed maintenance intervals. The maintenance test plan, also referred to as functional system testing, should include inputs, outputs,

communication, logic, and throughput timing tests. The functional tests are generally not component-level testing, rather overall system testing. Some of the input tests may need to be done ahead of overall system testing to the extent that the tests affect the overall performance. The test coordinator or coordinators need to have full knowledge of the intent of the scheme, isolation points, simulation scenarios, and restoration to normal procedures.

The concept is to validate the overall performance of the scheme, including the logic where applicable, to validate the overall throughput times against system modeling for different types of contingencies, and to verify scheme performance as well as the inputs and outputs."

Requirement R9:

The RAS database is a comprehensive record of all RAS existing in a Reliability Coordinator's area. The database enables the RC to provide other entities the ability to obtain high level information on existing RAS that can potentially impact the entities' operational and/or planning activities. Attachment 3 lists the minimum information required for the RAS database, which includes a summary of the RAS initiating conditions, corrective actions, and System issues being mitigated. This information allows an entity to evaluate the reliability need for requesting more detailed information from the RAS-entity identified in the database contact information. The Reliability Coordinator (RC) is the appropriate entity to maintain the database because the RC receives the required database information when a new or modified RAS is submitted for review.

Technical Justifications for Attachment 1 Content
Supporting Documentation for RAS Review

To perform an adequate review of the expected reliability implications of a remedial action scheme (RAS) it is necessary for the RAS owner(s) to provide a detailed list of information describing the RAS to the reviewing Reliability Coordinator (RC). While information may be needed from all owners of a RAS, a single RAS-owner (designated as the (RAS-entity)) is usually assigned the responsibility of compiling the RAS data and presenting it to the RC(s) review team. Other RAS-owners may participate in the review, if they choose.

The necessary data ranges from a general overview of the scheme to results of Transmission Planning studies that illustrate System performance before and after the RAS goes into service, as well as expected performance for unusual conditions, and whether certain adverse reliability impacts may occur. Possible adverse interactions, i.e. coordination between the RAS and other RAS and protection and control systems will be examined. This review can include wide ranging electrical design issues involving the specific hardware, logic, telecommunications and other relevant equipment and controls that make up the RAS.

Attachment 1

The following checklist identifies important RAS information for each new or functionally modified[3] RAS that the RAS-entity shall document and provide to the Reliability Coordinator (RC) for review pursuant to Requirement R1. When a RAS has been previously reviewed, only the proposed modifications to that RAS require review; however, it will be helpful to the reviewers if the RAS entity provides a summary of the previously approved RAS functionality.

I. General

1. Information such as maps, one-line drawings, substation and schematic drawings that identify the physical and electrical location of the RAS and related facilities.

    - Provide a description of the RAS to give an overall understanding of the functionality and a map showing the location of the RAS. Identify other protection and control systems requiring coordination with the RAS. See “RAS Design”, below, for additional information.
    - Provide a single line drawing(s) showing all sites involved. The drawing(s) should provide sufficient information to allow the RC review team to assess design reliability, and should include information such as the bus arrangement, circuit breakers, the associated switches, etc. For each site, indicate whether detection, logic, action, or a combination of these is present.

[3]Functionally Modified:
Any modification to a RAS beyond the replacement of components that preserve the original functionality is a functional modification.

2. Functionality of new RAS or proposed functional modifications to existing RAS and documentation of the pre- and post-modified functionality of the RAS.
3. The Corrective Action Plan (CAP) if RAS modifications are proposed in a CAP.
   [Reference NERC Reliability Standard PRC-012-2, Requirements R5 and R7]
   - The CAP is required if the periodic evaluation pursuant to Requirement R4, or the analysis of an actual RAS operation pursuant to Requirement R6 identified any performance deficieny(ies).

II. Functional Description and Transmission Planning Information

1. Contingencies and system conditions that the RAS is intended to remedy.
   [Reference NERC Reliability Standards PRC-012, R1.2 and PRC-013, R1.1]
   - The System conditions which would result if no RAS action occurred should be identified.
   - Include a description of the System conditions which should arm the RAS so as to be ready to take action upon subsequent occurrence of the critical system contingencies or other operating conditions when RAS action is intended to occur. If no arming conditions are required, this should also be stated.
   - Event based RAS are triggered by specific contingencies that initiate mitigating action. These contingencies should be identified. Condition based RAS may also be initiated by specific contingencies, but this is not always required.

2. The actions to be taken by the RAS in response to disturbance conditions.
   [Reference NERC Reliability Standards PRC-012, R1.2 and PRC-013, R1.2]
   - Mitigating actions are designed to result in acceptable System performance. These actions should be identified, including any time constraints and/or "backup" mitigating measures that may be required in case of a single RAS component failure.
3. A summary of technical studies, if applicable, demonstrating that the proposed RAS actions satisfy System performance objectives for the scope of System events and conditions that the RAS is intended to remedy. The technical studies should include information such as the study year(s), system conditions, and contingencies analyzed on which the RAS design is based, and when those technical studies were performed.
   [Reference NEC Reliability Standard PRC-014, R3.2]
   - Review the scheme purpose and impact to ensure it is (still) necessary, serves the intended purposes, and meets current performance requirements.
4. Information regarding any future system plans that will impact the RAS.
   [Reference NERC Reliability Standard PRC-014, R3.2]
   - The RC's other responsibilities under the NERC Reliability Standards focus on the Operating Horizon, rather than the Planning Horizon. As such, the RC is less likely to be aware of any longer range Plans that may have an impact on the proposed RAS. Such knowledge of future Plans is helpful to provide perspective on the capabilities of the RAS.
5. Documentation showing that inadvertent operation of the RAS satisfies the same performance requirements as those required for the contingency for which it was designed

or, if no performance requirements apply, the inadvertent operation of the RAS satisfies the requirements of Category P7 in Table 1 of NERC Reliability Standard TPL-001-4, or its successor.
[Reference NERC Reliability Standard PRC-012, R1.4]

6. An evaluation indicating that the RAS avoids adverse interactions with other RAS, and protection and control systems.
   [Reference NERC Reliability Standards PRC-012, R1.5 and PRC-014, R3.4]
   - RAS are complex schemes that typically take action which trips load or generation or re-configures the system. Many RAS depend on sensing specific system configurations to determine whether they need to arm or take actions. Examples include: overlapping actions among RAS that may have the potential to result in cascading, unless coordinated, RAS that reconfigure the System also change the available fault duty, which can affect distance relay overcurrent ("fault detector") supervision and ground overcurrent protection coordination.

7. Identification of other affected RCs.
   - This information is needed to aid in information exchange among all affected entities and coordination of the RAS with other RAS and protection and control systems.

III. Implementation

1. Documentation describing the equipment used for detection, telecommunications, transfer trip, logic processing, and monitoring, whichever are applicable.

   Logic Processing
   - All RAS require some form of logic processing to determine the action to take when the scheme is triggered. Required actions are always scheme dependent. Different actions may be required at different arming levels or for different contingencies. Scheme logic may be achievable by something as simple as wiring a few auxiliary relay contacts or by much more complex logic processing.

   - Platforms that have been used reliably and successfully, include programmable logic controllers (PLCs) in various forms, personal computers (PCs), microprocessor protective relays, remote terminal units (RTUs), and logic processors. Single-function relays have been used historically to implement RAS, but this approach is now less common except for very simple new RAS or minor additions to existing RAS.

   Communications Channels
   - Communication channels used for sending and receiving RAS information between sites and/or transfer trip devices must meet at least the same criteria as for other relaying protection communication channels. Discuss performance of any non-deterministic communication systems used (such as Ethernet).

   - The scheme logic should be designed so that loss of the channel, noise, or other channel failure will not result in a false operation of the scheme.

- It is highly desirable that the channel equipment and communications media (power line carrier, microwave, optical fiber, etc.) be owned and maintained by the RAS owner, or perhaps leased from another entity familiar with the necessary reliability requirements. All channel equipment must be monitored and alarmed to the dispatch center so that timely diagnostic and repair action shall be taken place upon failure.
- Communication channels shall be well labeled or identified so that the personnel working on the channel can readily identify the proper circuit. Channels between entities shall be identified with a common name at all terminals.

2. Information on detection logic and settings/parameters that control the operation of the RAS. [Reference NERC Reliability Standards PRC-012, R1.2 and PRC-013, R1.3]

   Detection and initiating devices must be designed to be as secure as possible. The following discussion identifies several types of devices that have been used as disturbance detectors:

   - Line open status (event detectors),
   - Protective relay inputs and outputs (event and parameter detectors),
   - Transducer and IED (analog) inputs (parameter and response detectors),
   - Rate of change (parameter and response detectors).

   Several methods to determine line open status are in common use, often in combination:

   - Auxiliary switch contacts from circuit breakers and disconnect switches (52b, 89b),
   - Undercurrent detection (a low level indicates an outage),
   - Breaker trip bus monitoring, and
   - Other detectors such as angle, voltage, power, frequency, rate of change of these, out of step, etc.

3. Documentation showing that any device used to perform RAS function(s), in addition to other functions such as protective relaying or SCADA, does not compromise the reliability of the RAS when the device is not in service or is being maintained.

   - In this context, a multifunction device (e.g. microprocessor-based relay) is a single device that is used to perform the function of a RAS in addition to protective relaying and/or SCADA simultaneously. It is important that other applications in the multifunction device do not compromise the functionality of the RAS when the device is in service or when is being maintained. The following list outlines concerns to be addressed when the RAS function is applied in the same microprocessor-based relay as the protection function:

     - a) Describe how the multifunction device is applied in the RAS.
     - b) Show the general arrangement and describe how the multi-function device is labeled in the design and application, so as to identify the RAS and other device functions.

- c) Describe the procedures used to isolate the RAS function from other functions in the device.
- d) Describe the procedures used when each multifunction device is removed from service and whether any other coordination with other protection is required.
- e) Describe how each multifunction device is tested, both for commissioning and during periodic maintenance testing, with regard to each function of the device.
- f) Describe how overall periodic RAS functional and throughput tests are performed if multifunction devices are used for both local protection and RAS.
- g) Describe how upgrades to the multifunction device, such as firmware upgrades, are accomplished. How is the RAS function taken into consideration?

o Other devices usually not considered multifunction devices such as auxiliary relays, control switches, and instrument transformers may serve multiple purposes such as protection and RAS. Similar concerns apply for these applications as noted above.

4. Documentation showing that a single component failure in a RAS does not prevent the BES from meeting the same performance requirements as those required for the System events and conditions for which the RAS was designed. The documentation should describe or illustrate how the implementation design achieves this objective.
   [Reference NERC Reliability Standard PRC-012, R1.3]

The critical part of PRC-012 R1.3 philosophy is that a RAS should be designed so that a "single [RAS] component failure … does not prevent … meeting the performance requirements defined in Reliability Standards". The philosophy regarding "single component failure" from PRC-012-0 is carried over in to this standard. Redundancy is one way to implement the "single component failure" philosophy but other methods are acceptable.

The following list are examples of RAS components that could be considered in the single component failure analysis:

- Any single ac secondary current or voltage source and/or related inputs to the RAS.
- Any single device used to measure electrical quantities used by the RAS.
- Any single communication channel and/or any single piece of related communication equipment used by the RAS.
- Any single computer or programmable logic device used to analyze information and provide RAS operational output.
- Any single element of the dc control circuitry that is used for the RAS, including breaker closing circuits.
- Any single auxiliary relay or auxiliary device used by the RAS.
- Any single breaker trip coil for any breaker operated by the RAS.
- Any single station battery or single charger, or other single dc source, where central monitoring is not provided for both low voltage and battery open conditions.

Duplication of the listed components is a way to achieve redundancy and meet the "single component failure" requirement. For schemes performing distributed actions (e.g. load shedding or generation rejection at multiple locations), over arming (providing extra corrective action to cover failure to operate of one critical component) can also be an effective option, as long as it does not compromise the performance of the system. Other coordinated Protection Systems, such as breaker failure, may be used as long as the System performance resulting from breaker failure is still acceptable under the original contingency the RAS was designed to mitigate

IV. RAS Retirement

The following checklist identifies important RAS information for each existing RAS to be retired that the RAS-entity shall document and provide to the Reliability Coordinator for review pursuant to Requirement R1.

1. Information necessary to ensure that the Reliability Coordinator is able to understand the physical and electrical location of the RAS and related facilities.
2. A summary of technical studies, if applicable, upon which the decision to retire the RAS is based.
3. Anticipated date of RAS retirement.

Technical Justifications for Attachment 3 Content
Database Information

Attachment 3 contains the minimum information the RC must consolidate into its database for each RAS in its area.

1. RAS name.
   - The usual name used to identify the RAS.

2. RAS-entity and contact information.
   - A reliable phone number or email address should be included to contact the RAS-entity if more information is needed (e.g. modeling information per requirement R11). At a minimum, the name of the RAS-entity responsible for the RAS information.

3. Expected or actual in-service date; most recent (Requirement R3) RC-approval date; most recent 60 full calendar-month (Requirement R4) evaluation date; and, date of retirement, if applicable.
   - Specify each applicable date.

4. System performance issue or reason for installing the RAS (*e.g.*, thermal overload, angular instability, poor oscillation damping, voltage instability, under-/over-voltage, slow voltage recovery).
   - A short description of the reason for installing the RAS is sufficient, as long as the main system issues addressed by the RAS can be identify by someone with a reliablilty need.

5. Description of the contingencies or System conditions for which the RAS was designed (initiating conditions).
   - A high level summary of the conditions/contingencies is expected. Not all combinations of conditions are required to be listed.

6. Corrective action taken by the RAS.
   - For schemes shedding load or generation, the maximum amount of MW should be included.

7. Any additional explanation relevant to high level understanding of the RAS.
   - If deemed necessary, any additional information can be included in this section, but is not mandatory.

Project 2015-06 – Interconnection Reliability Operations and Coordination

Mapping Document | Updated May 2015

This mapping document shows the translation of Requirements in the following currently-enforceable standards to revised standards developed in Project 2015-06:

- IRO-006-EAST-1 —Transmission Loading Relief Procedure for the Eastern Interconnection
- IRO-009-1 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities

Standard IRO-006-EAST-1 — Transmission Loading Relief Procedure for the Eastern Interconnection	
Requirement in Approved Standard	**Proposed Language in New Standard or Comment**
R1. When acting or instructing others to act to mitigate the magnitude and duration of the instance of exceeding an IROL within that IROL's TV, each Reliability Coordinator shall initiate, prior to or concurrently with the initiation of the Eastern Interconnection TLR procedure (or continuing management of this procedure if already initiated), one or more of the following actions: • Inter-area redispatch of generation • Intra-area redispatch of generation • Reconfiguration of the transmission system • Voluntary load reductions (e.g., Demand-side Management) • Controlled load reductions (e.g., load shedding)	Standard IRO-006-EAST-2 — Transmission Loading Relief Procedure for the Eastern Interconnection ***Rationale for recommendation to retire Requirement R1:*** *The IRO standard drafting team (IRO SDT) agrees with the FYRT's assertion that IRO-006-EAST-1 Requirement R1 is redundant with IRO-008-1, Requirement R3, and IRO-009-1, Requirement R4, and that the requirements in IRO-008-1 and IRO-009-1 are results based and specify a reliability objective to be achieved. The IRO SDT further agrees with the Five Year Review Team's (FYRT) conclusion that IRO-006-EAST-1 Requirement R1 simply provides a list of actions to be taken without any parameters for their use.*
R2. To ensure operating entities are provided with information needed to maintain an awareness of changes to the Transmission System, when initiating the Eastern Interconnection TLR procedure to prevent or mitigate an SOL or IROL exceedance, and at least every clock hour (with the exception of TLR-1, where an hourly update is not required) after initiation up to and including the hour when the TLR level has been	Standard IRO-006-EAST-2 — Transmission Loading Relief Procedure for the Eastern Interconnection **R1.** Each Reliability Coordinator that initiates the Eastern Interconnection TLR procedure to prevent or mitigate an SOL or IROL exceedance shall identify the TLR level and the congestion management actions to be implemented, and shall update this information at least every clock hour (except TLR-1) after initiation up to and including the hour when the TLR level has been identified as TLR Level 0.[1]

Standard IRO-006-EAST-1 — Transmission Loading Relief Procedure for the Eastern Interconnection	
Requirement in Approved Standard	**Proposed Language in New Standard or Comment**
identified as TLR Level 0, the Reliability Coordinator shall identify: **2.1.** A list of congestion management actions to be implemented, and **2.2.** One of the following TLR levels: TLR-1, TLR-2, TLR-3A, TLR-3B, TLR-4, TLR-5A, TLR-5B, TLR-6, TLR-0	_____ [1] For more information on TLR levels, please see "Implementation Guideline for Reliability Coordinators: Eastern Interconnection TLR Levels Reference Document." ***Rationale for revisions to new Requirement R1 (previously Requirement R2):*** *The IRO SDT provided edits to improve clarity and to incorporate and simplify the sub-requirements into the main requirement.*
R3. Upon the identification of the TLR level and a list of congestion management actions to be implemented, the Reliability Coordinator initiating this TLR procedure shall: **3.1.** Notify all Reliability Coordinators in the Eastern Interconnection of the identified TLR level **3.2.** Communicate the list of congestion management actions to be implemented to 1.) all Reliability Coordinators in the Eastern Interconnection, and 2.) those Reliability Coordinators in other Interconnections responsible for curtailing Interchange Transactions crossing Interconnection boundaries identified in the list of congestion management actions. **3.3.** Request that the congestion management actions identified in Requirement R2, Part 2.1 be implemented by: 1.) Each Reliability Coordinator associated with a Sink Balancing Authority for which Interchange Transactions are to be curtailed,	Standard IRO-006-EAST-2 — Transmission Loading Relief Procedure for the Eastern Interconnection ***Rationale for recommendation to retire Requirement R3:*** *The IRO SDT agrees with the FYRT's determination that the intent of Requirement R3 is not to define a curtailment process when the Interchange Distribution Calculator (IDC) is compromised or unavailable. In the event of an IDC failure, TLR action would be very limited resulting in manual curtailments and other manual actions to preserve the reliability of the Bulk Electric System. The IRO SDT further agrees with the FYRT's assertion that Requirement R3 contains actions that are automatically generated via the IDC tool and sent to proper entities upon issuance of the TLR. This requirement should be removed from the standard, as it meets Paragraph 81 Criterion B1 – Administrative.*[1]

[1] Paragraph 81 Criteria available at: http://www.nerc.com/pa/Stand/Project%20200812%20Coordinate%20Interchange%20Standards%20DL/Paragraph_81_Criteria.pdf.

Standard IRO-006-EAST-1 — Transmission Loading Relief Procedure for the Eastern Interconnection	
Requirement in Approved Standard	**Proposed Language in New Standard or Comment**
2.) Each Reliability Coordinator associated with a Balancing Authority in the Eastern Interconnection for which Network Integration Transmission Service or Native Load is to be curtailed, and 3.) Each Reliability Coordinator associated with a Balancing Authority in the Eastern Interconnection for which its Market Flow is to be curtailed.	
R4. Each Reliability Coordinator that receives a request as described in Requirement R3, Part 3.3. shall, within 15 minutes of receiving the request, implement the congestion management actions requested by the issuing Reliability Coordinator as follows: • Instruct its Balancing Authorities to implement the Interchange Transaction schedule change requests. • Instruct its Balancing Authorities to implement the Network Integration Transmission Service and Native Load schedule changes for which the Balancing Authorities are responsible. • Instruct its Balancing Authorities to implement the Market Flow schedule changes for which the Balancing Authorities are responsible. • If an assessment determines shows that one or more of the congestion management actions communicated in Requirement R3, Part 3.3 will result in a reliability concern or will be ineffective, the Reliability Coordinator may replace those specific actions with alternate congestion management actions, provided that:	Standard IRO-006-EAST-2 — Transmission Loading Relief Procedure for the Eastern Interconnection **R2.** Each Reliability Coordinator with a Sink Balancing Authority that must implement congestion management actions pursuant to the Eastern Interconnection TLR procedure shall instruct the Sink Balancing Authority to implement the congestion management actions within 15 minutes of receiving the request from the issuing Reliability Coordinator, subject to the following exception: • Should an assessment determine that one or more of the congestion management actions communicated will result in a reliability concern or will be ineffective, the Reliability Coordinator with a Sink Balancing Authority shall coordinate alternate congestion management actions with the issuing Reliability Coordinator. ***Rationale for Revisions to new Requirement R2 (previously Requirement R4):*** *The IRO SDT provided edits to improve clarity and to incorporate and simplify some of the bullets into the main requirement, and modified the remaining bullet to be a requirement instead of a passive statement.*

Standard IRO-006-EAST-1 — Transmission Loading Relief Procedure for the Eastern Interconnection	
Requirement in Approved Standard	**Proposed Language in New Standard or Comment**
• The alternate congestion management actions have been agreed to by the initiating Reliability Coordinator, and • The assessment shows that the alternate congestion management actions will not adversely affect reliability.	

Standard IRO-009-1 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities	
Requirement in Approved Standard	**Proposed Language in New Standard or Comment**
R1. For each IROL (in its Reliability Coordinator Area) that the Reliability Coordinator identifies one or more days prior to the current day, the Reliability Coordinator shall have one or more Operating Processes, Procedures, or Plans that identify actions it shall take or actions it shall direct others to take (up to and including load shedding) that can be implemented in time to prevent exceeding those IROLs.	Standard IRO-009-2 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities **R1.** For each IROL (in its Reliability Coordinator Area) that the Reliability Coordinator identifies one or more days prior to the current day, the Reliability Coordinator shall have one or more Operating Processes, Procedures, or Plans that identify actions the Reliability Coordinator shall take or actions the Reliability Coordinator shall direct others to take (up to and including load shedding): **1.1** That can be implemented in time to prevent the identified IROL exceedance. **1.2** To mitigate the magnitude and duration of an IROL exceedance such that the IROL is relieved within the IROL's Tv.
R2. For each IROL (in its Reliability Coordinator Area) that the Reliability Coordinator identifies one or more days prior to the current day, the Reliability Coordinator shall have one or more Operating Processes, Procedures, or Plans that identify actions it shall take or actions it shall direct others to take (up to and including load shedding) to mitigate the magnitude and duration of exceeding that IROL such that the IROL is relieved within the IROL's Tv.	Standard IRO-009-2 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities ***Rationale for revisions to this Requirement (previously Requirement R2):*** *The IRO SDT revised this requirement by combining IRO-009-1 Requirements R1 and R2 to form one requirement, Requirement R1, with two subparts to make the requirements more concise, as both requirements contained similar language.*
R3. When an assessment of actual or expected system conditions predicts that an IROL in its Reliability Coordinator Area will be exceeded, the Reliability Coordinator shall implement one or more Operating Processes, Procedures or Plans (not limited to the Operating Processes, Procedures, or Plans developed for Requirements R1) to prevent exceeding that IROL.	Standard IRO-009-2 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities **R2.** Each Reliability Coordinator shall initiate one or more Operating Processes, Procedures, or Plans (not limited to the Operating Processes, Procedures, or Plans developed for Requirement R1) that are intended to prevent an IROL exceedance, as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment. ***Rationale for revisions to new Requirement R2 (previously Requirement R3):*** *The IRO SDT revised the language of this requirement to improve clarity as well as consistency with similar*

Standard IRO-009-1 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities	
Requirement in Approved Standard	**Proposed Language in New Standard or Comment**
	NERC Board of Trustees (Board) approved standards, such as, TOP standard revisions (TOP-001-3 R14); "IROL exceedance," "Real Time monitoring," and "Real Time Assessments."
R4. When actual system conditions show that there is an instance of exceeding an IROL in its Reliability Coordinator Area, the Reliability Coordinator shall, without delay, act or direct others to act to mitigate the magnitude and duration of the instance of exceeding that IROL within the IROL's Tv.	Standard IRO-009-2 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities **R3.** Each Reliability Coordinator shall act or direct others to act so that the magnitude and duration of an IROL exceedance is mitigated within the IROL's Tv, as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment. ***Rationale for Revisions to Requirement R3 (previously Requirement R4):*** *The IRO SDT removed the term "without delay" from the requirement upon determining that the point of time at which the requirement is triggered is inherent in the requirement itself. The IRO SDT also revised the language of this requirement to improve clarity as well as consistency with similar Board approved standards, such as, TOP standard revisions (TOP-001-3 R14); "IROL exceedance," "Real Time monitoring," and "Real Time Assessments."*
R5. If unanimity cannot be reached on the value for an IROL or its Tv, each Reliability Coordinator that monitors that Facility (or group of Facilities) shall, without delay, use the most conservative of the values (the value with the least impact on reliability) under consideration.	Standard IRO-009-2 — Reliability Coordinator Actions to Operate Within IROLs - Responsibilities and Authorities **R4.** Each Reliability Coordinator shall operate to the most limiting IROL and Tv in instances where there is a difference in an IROL or its Tv between Reliability Coordinators that are responsible for that Facility (or group of Facilities). ***Rationale for revisions to Requirement R4 (previously Requirement R5):*** *The IRO SDT revised the language of this requirement for clarity as well as consistency with similar Board approved standards, such as TOP standard revisions (TOP-001-3 R18). The IRO SDT retained clarifying language to limit applicability to appropriate affected RCs.*

Project 2015-06 Interconnection Reliability Operations and Coordination
IRO-006-EAST-2

Standards Involved

Approval:

- IRO-006-EAST-2 – Transmission Loading Relief Procedure for the Eastern Interconnection

Retirement:

- IRO-006-EAST-1 – Transmission Loading Relief Procedure for the Eastern Interconnection

Prerequisite Approvals

N/A

Background

Project 2015-06 Interconnection Reliability Operations and Coordination (Project) was initiated to implement the Project 2012-09 Interconnection Reliability Operations Five-Year Review Team (FYRT) recommendations to revise IRO-006-EAST-1 and IRO-009-1.

The FYRT originally reviewed IRO-003-2, IRO-004-2, IRO-005-4, IRO-006-5, IRO-006-East, IRO-008-1, IRO-009-1 and IRO-010-1a, and recommended revising all of these standards except for IRO-006-5, which was reaffirmed by the NERC Board of Trustees (Board). Additionally, Project 2014-03 Revisions to TOP and IRO Standards, retired IRO-003-2, IRO-004-2, IRO-005-4, IRO-008-1, and IRO-010-1a, leaving only IRO-006-EAST-1 and IRO-009-1 with outstanding recommendations for revision.

Based on the FYRT's recommendation to revise IRO-006-EAST-1 and industry comments in response to the 30-day informal comment period for the Project ending on April 15, 2015, the Project standard drafting team (SDT) recommends revising the standard as reflected in the posted documents.

General Considerations

Reliability Standard IRO-006-EAST-2 is proposed for approval to address the recommendations of the five-year review and industry comments.

Effective Date

Reliability Standard IRO-006-EAST-2 shall become effective on the first day of the second calendar quarter after the date that the standard is approved by an applicable governmental authority or as otherwise provided for in a jurisdiction where approval by an applicable governmental authority is

required for a standard to go into effect. Where approval by an applicable governmental authority is not required, the standard shall become effective the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Retirement of Existing Standards

Reliability Standard IRO-006-EAST-1 shall be retired at midnight of the day immediately prior to the effective date of IRO-006-EAST-2 in the particular jurisdiction in which the revised standard is becoming effective.

Implementation Plan

Reliability Standard IRO-006-EAST-1 will continue to be implemented pursuant to the Implementation Plan for IRO-006-EAST-1 and is incorporated herein by reference.

Cross References

The Implementation Plan for IRO-006-EAST-1 is available here.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Description of Current Draft

This version of Reliability Standard IRO-006-EAST is posted for a 45-day concurrent comment and ballot period to address the recommendations of the Project 2012-09 Interconnected Reliability Operations Five-Year Review Team. That review resulted in a recommended drafting effort, which is being conducted by the Project 2015-06 Interconnection Reliability Operations and Coordination standard drafting team.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	March 11, 2015
SAR posted for comment	March 16 – April 15, 2015

Anticipated Actions	Anticipated Dates
45-day formal or informal comment period with ballot	May – July 2015
Final ballot	July 2015
NERC Board (Board) adoption	November 2015

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s): None.

The rationale boxes will be moved to the Supplemental Material Section of the standard after the standard is adopted by the NERC Board of Trustees.

A. Introduction

1. **Title: Transmission Loading Relief Procedure for the Eastern Interconnection**
2. **Number:** IRO-006-EAST-~~1~~2
3. **Purpose:** To ensure coordinated action between Reliability Coordinators within the Eastern ~~provide an~~ Interconnection~~-wide~~ when implementing transmission loading relief procedures (TLR) for the Eastern Interconnection ~~that can be used~~ to prevent ~~and/~~or ~~mitigate~~ manage potential or actual System Operating Limit (SOL) and Interconnection Reliability Operating Limit (IROL) exceedances to maintain reliability of the Bulk Electric System (BES).
4. **Applicability:**
   - **4.1.** Reliability Coordinators in the Eastern Interconnection.
5. **Proposed Effective Date:** See the Implementation Plan for IRO-006-EAST-2.~~First day of the first calendar quarter following the date this standard is approved by applicable regulatory authorities, or in those jurisdictions where regulatory approval is not required, the standard becomes effective on the first day of the first calendar quarter after the date this standard is approved by the NERC Board of Trustees.~~

B. Requirements

Rationale for recommendation to retire Requirement R1: The standard drafting team (IRO SDT) agrees with the FYRT's assertion that IRO-006-EAST-1 Requirement R1 is redundant with IRO-008-1, Requirement R3, and IRO-009-1, Requirement R4, and that the requirements in IRO-008-1 and IRO-009-1 are results based and specify a reliability objective to be achieved. The IRO SDT further agrees with the FYRT's conclusion that IRO-006-EAST-1 Requirement R1 simply provides a list of actions to be taken without any parameters for their use.

~~**R1.** When acting or instructing others to act to mitigate the magnitude and duration of the instance of exceeding an IROL within that IROL's TV, each Reliability Coordinator shall initiate, prior to or concurrently with the initiation of the Eastern Interconnection TLR procedure (or continuing management of this procedure if already initiated), one or more of the following actions: [*Violation Risk Factor: High*] [*Time Horizon: Real-time Operations*]~~

- ~~Inter-area redispatch of generation~~
- ~~Intra-area redispatch of generation~~
- ~~Reconfiguration of the transmission system~~
- ~~Voluntary load reductions (e.g., Demand-side Management)~~

- ~~Controlled load reductions (e.g., load shedding)~~

Rationale for revisions to new Requirement R1 (previously Requirement R2): The IRO SDT provided edits to improve clarity and to incorporate and simplify the sub-requirements into the main requirement.

R1~~2~~. Each Reliability Coordinator that initiates~~To ensure operating entities are provided with information needed to maintain an awareness of changes to the Transmission System, when initiating~~ the Eastern Interconnection TLR procedure to prevent or mitigate an SOL or IROL exceedance~~,~~ shall identify the TLR level and the congestion management actions to be implemented, and shall update this information at least every clock hour (~~with the~~ except~~ion of~~ TLR-1~~, where an hourly update is not required~~) after initiation up to and including the hour when the TLR level has been identified as TLR Level 0.[1]~~, the Reliability Coordinator shall identify:~~ [*Violation Risk Factor: Medium*] [*Time Horizon: Real-time Operations*]

~~**2.1.** A list of congestion management actions to be implemented, and~~

~~One of the following TLR levels: TLR-1, TLR-2, TLR-3A, TLR-3B, TLR-4, TLR-5A, TLR-5B, TLR-6, TLR-0~~[1]

~~[1] For more information on TLR levels, please see "Implementation Guideline for Reliability Coordinators: Eastern Interconnection TLR Levels Reference Document."~~

[1] For more information on TLR levels, please see "Implementation Guideline for Reliability Coordinators: Eastern Interconnection TLR Levels Reference Document."

Rationale for recommendation to retire Requirement R3: The IRO SDT agrees with the FYRT's determination that the intent of Requirement R3 is not to define a curtailment process when the IDC is compromised or unavailable. In the event of an IDC failure, TLR action would be very limited resulting in manual curtailments and other manual actions to preserve the reliability of the Bulk Electric System. The IRO SDT further agrees with the FYRT's assertion that Requirement R3 contains actions that are automatically generated via the IDC tool and sent to proper entities upon issuance of the TLR. This requirement should be removed from the standard, as it meets Paragraph 81 Criterion B1 – Administrative.

~~**R3.** Upon the identification of the TLR level and a list of congestion management actions to be implemented, the Reliability Coordinator initiating this TLR procedure shall: [*Violation Risk Factor: Medium*] [*Time Horizon: Real-time Operations*]~~

~~**3.1.** Notify all Reliability Coordinators in the Eastern Interconnection of the identified TLR level~~

~~**3.2.** Communicate the list of congestion management actions to be implemented to 1.) all Reliability Coordinators in the Eastern Interconnection, and 2.) those Reliability Coordinators in other Interconnections responsible for curtailing Interchange Transactions crossing Interconnection boundaries identified in the list of congestion management actions.~~

~~**3.3.** Request that the congestion management actions identified in Requirement R2, Part 2.1 be implemented by:~~

~~1.) Each Reliability Coordinator associated with a Sink Balancing Authority for which Interchange Transactions are to be curtailed,~~

~~2.) Each Reliability Coordinator associated with a Balancing Authority in the Eastern Interconnection for which Network Integration Transmission Service or Native Load is to be curtailed, and~~

~~3.) Each Reliability Coordinator associated with a Balancing Authority in the Eastern Interconnection for which its Market Flow is to be curtailed.~~

Rationale for Revisions to new Requirement R2 (previously Requirement R4): The IRO SDT provided edits to improve clarity and to incorporate and simplify some of the bullets into the main requirement, and modified the remaining bullet to be a requirement instead of a passive statement.

R4~~2~~. Each Reliability Coordinator with a Sink Balancing Authority that must implement congestion management actions pursuant to the Eastern

Interconnection TLR procedure ~~that receives a request as described in Requirement R3, Part 3.3.~~ shall instruct the Sink Balancing Authority to implement the congestion management actions~~,~~ within 15 minutes of receiving the request~~, implement the congestion management actions requested by~~from the issuing Reliability Coordinator, subject to the following exception: ~~as follows:~~ [*Violation Risk Factor: High*] [~~*Time Horizon: Real-time Operations*~~]

- ~~Instruct its Balancing Authorities to implement the Interchange Transaction schedule change requests.~~
- ~~Instruct its Balancing Authorities to implement the Network Integration Transmission Service and Native Load schedule changes for which the Balancing Authorities are responsible.~~
- ~~Instruct its Balancing Authorities to implement the Market Flow schedule changes for which the Balancing Authorities are responsible.~~
- Should ~~If~~ an assessment determine~~s shows~~ that one or more of the congestion management actions communicated ~~in Requirement R3, Part 3.3~~ will result in a reliability concern or will be ineffective, the Reliability Coordinator with a Sink Balancing Authority shall coordinate alternate congestion management actions with the issuing Reliability Coordinator ~~the Reliability Coordinator may replace those specific actions with alternate congestion management actions, provided that:~~.

  ~~The alternate congestion management actions have been agreed to by the initiating Reliability Coordinator, and~~

  ~~The assessment shows that the alternate congestion management actions will not adversely affect reliability.~~

~~Measures~~

~~C. M1. Each Reliability Coordinator shall provide evidence (such as dated logs, voice recordings, or other information in electronic or hard-copy format) that when acting or instructing others to act to mitigate the magnitude and duration of the instance of exceeding an IROL within that IROL's Tv, the Reliability Coordinator initiated one or more of the actions listed in R1 prior to or concurrently with the initiation of the Eastern Interconnection TLR procedure (or continuing management of this procedure if already initiated)(R1).~~

M21. Each Reliability Coordinator shall provide evidence (such as dated logs, voice recordings, or other information in electronic or hard-copy format) that at the time it initiated the Eastern Interconnection TLR procedure, and at least every clock hour after initiation up to and including the hour when the TLR level was identified as TLR Level 0, the Reliability Coordinator identified both the TLR Level and a list of congestion management actions to be implemented in accordance with Requirement R1~~(R2)~~.

~~**M3.** Each Reliability Coordinator shall provide evidence (such as dated logs, voice recordings, or other information in electronic or hard-copy format) that after it identified a TLR level and a list of congestion management actions to take, it 1.) notified all Reliability Coordinators in the Eastern Interconnection of the TLR Level, 2.) communicated the list of actions to all Reliability Coordinators in the Eastern Interconnection and those Reliability Coordinators in other Interconnections responsible for curtailing Interchange Transactions crossing Interconnection boundaries identified in the list of congestion management actions, and 3.) requested the Reliability Coordinators identified in Requirement R3 Part 3.2 to implement the congestion management actions identified in Requirement R2 Part 2.1 (R3).~~

M42.~~.~~ Each Reliability Coordinator with a Sink Balancing Authority that must implement congestion management actions pursuant to the Eastern Interconnection TLR procedure shall provide evidence (such as dated logs, voice recordings, or other information in electronic or hard-copy format) that within fifteen minutes of the receipt of a request ~~as described in R3~~, the Reliability Coordinator complied with the request by either 1~~.~~) instructing the Sink Balancing Authority to implement the congestion management actions~~implementing the communicated congestion management actions~~ requested by the issuing Reliability Coordinator, or 2~~.~~) implementing none or some of the communicated congestion management actions requested by the issuing Reliability Coordinator, and replacing the remainder with alternate congestion management actions if assessment showed that some or all of the requested congestion management actions ~~communicated in R3~~ would have resulted in a reliability concern or would have been ineffective~~., the alternate congestion management actions were agreed to by the initiating Reliability Coordinator,, and assessment showed that the alternate congestion management actions would not adversely affect reliability~~ in accordance with Requirement R2~~(R4)~~.

1. **Compliance Monitoring Process**

1.1. Compliance Enforcement Authority:

"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1 and Requirement R2, the Reliability Coordinator shall maintain evidence to show compliance with Requirement R1 and Requirement R2 for the past 12 months plus the current month.

If a Reliability Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program

As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Additional Compliance Information

None.

~~**1.1. Compliance Enforcement Authority**~~

~~Regional Entity.~~

~~**1.2. Compliance Monitoring and Enforcement**~~

~~Processes: The following processes may be used:~~

~~Compliance Audits~~

~~Self-Certifications~~

~~Spot Checking~~

~~Compliance Violation Investigations~~

~~Self-Reporting~~

~~Complaints~~

~~**1.3.** Data Retention~~

~~The Reliability Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:~~

~~The Reliability Coordinator shall maintain evidence to show compliance with R1, R2, R3, and R4 for the past 12 months plus the current month.~~

~~If a Reliability Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant.~~

~~The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.~~

~~**1.4.** Additional Compliance Information~~

~~None.~~

3. Violation Severity Levels

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1				When acting or instructing others to act to mitigate the magnitude and duration of the instance of exceeding an IROL within that IROL's T_V, the Reliability Coordinator did not initiate one or more of the actions listed under R1 prior to or in conjunction with the initiation of the Eastern Interconnection TLR procedure (or continuing management of this procedure if already initiated).

R~~2~~1	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for one clock hour during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for two clock hours during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for three clock hours during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for four or more clock hours during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
R42				The responding Reliability Coordinator did not, within 15 minutes of receiving a request, either 1.) instruct the Sink Balancing Authority to implement all the requested congestion management actions, or 2.) implement none or some of the requested congestion management actions and replace the remainder with coordinate alternate

R #	Lower VSL	Moderate VSL	High VSL	Severe VSL
				congestion management actions with the issuing Reliability Coordinator, provided that: assessment showed that the actions replaced would have resulted in a reliability concern or would have been ineffective.~~, the alternate congestion management actions were agreed to by the initiating Reliability Coordinator, and assessment determined that the alternate congestion management actions would not adversely affect reliability.~~

Implementation Guideline for Reliability Coordinators:
Eastern Interconnection TLR Levels

The listed system conditions examples are intended to assist the Reliability Coordinator in determining what level of TLR to call. The Reliability Coordinator has the discretion to choose any of these levels regardless of the examples listed, provided the Reliability Coordinator has reliability reasons to take such action. TLR levels are neither required nor expected to be issued in numerical order of level.

Table 1: Eastern Interconnection TLR Levels

Level	Examples of Possible System Conditions
TLR-1	• At least one Transmission Facility is expected to approach or exceed its SOL or IROL within 8 hours.
TLR-2	• At least one Transmission Facility is approaching or is at its SOL or IROL. o Analysis shows that holding new and increasing non-firm Interchange Transactions and energy flows for the next hour can prevent exceeding this SOL or IROL.
TLR-3a	• At least one Transmission Facility is expected to exceed its SOL or IROL within the next hour. o Analysis shows that full or partial curtailment or reallocation[2] of non- firm Interchange Transactions and energy flows can prevent exceeding this SOL and IROL.
TLR-3b	• At least one Transmission Facility is exceeding its SOL or IROL; or • At least one Transmission Facility is expected to exceed its SOL or IROL within the current hour. o Analysis shows that full or partial curtailment or reallocation[2] of non- firm Interchange Transactions and energy flows can prevent exceeding this SOL or IROLs.
TLR-4	• At least one Transmission Facility is expected to exceed its SOL or IROL. o Analysis shows that full curtailment of non-firm Interchange Transactions and energy flows, or reconfiguration of the transmission system can prevent exceeding this SOL or IROL.
TLR-5a	• At least one Transmission Facility is expected to exceed its SOL or IROL within the next hour. o Analysis shows that the following actions can prevent exceeding the SOL or IROL: ▪ Full curtailment non-firm Interchange Transactions and energy flows, and ▪ Reconfiguration of the transmission system, if possible, and ▪ Full or partial curtailment or reallocation[2] of firm Interchange Transactions and energy flows.

[2] "Reallocation" is a term defined within the NAESB TLR standards.

Level	Examples of Possible System Conditions
TLR-5b	• At least one Transmission Facility is exceeding its SOL or IROL; or • At least one Transmission Facility is expected to exceed its SOL or IROL within the current hour. o Analysis shows that the following actions can prevent exceeding the SOL or IROL: ▪ Full curtailment of non-firm Interchange Transactions and energy flows, and ▪ Reconfiguration of the transmission system, if possible; and ▪ Full or partial curtailment or reallocation[2] of firm Interchange Transactions and energy flows.
TLR-6	• At least one Transmission Facility is exceeding its SOL or IROL; or • At least one Transmission Facility is expected to exceed its SOL or IROL upon the removal from service of a generating unit or another transmission facility.
TLR-0	• No transmission facilities are expected to approach or exceed their SOL or IROL within 8 hours, and the Interconnection-wide transmission loading relief procedure may be terminated

Enforcement Dates: Standard IRO-006-EAST-1 — Transmission Loading Relief Procedure for the Eastern Interconnection

United States

Standard	Requirement	Enforcement Date	Inactive Date
IRO-006-EAST-1	All	07/01/2011	

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Description of Current Draft

This version of Reliability Standard IRO-006-EAST is posted for a 45-day concurrent comment and ballot period to address the recommendations of the Project 2012-09 Interconnected Reliability Operations Five-Year Review Team. That review resulted in a recommended drafting effort, which is being conducted by the Project 2015-06 Project 2015-06 Interconnection Reliability Operations and Coordination standard drafting team.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	March 11, 2015
SAR posted for comment	March 16 – April 15, 2015

Anticipated Actions	Anticipated Dates
45-day formal or informal comment period with ballot	May – July 2015
Final ballot	July 2015
NERC Board (Board) adoption	November 2015

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s): None.

The rationale boxes will be moved to the Supplemental Material Section of the standard after the standard is adopted by the NERC Board of Trustees.

A. Introduction

1. **Title:** **Transmission Loading Relief Procedure for the Eastern Interconnection**
2. **Number:** IRO-006-EAST-2
3. **Purpose:** To ensure coordinated action between Reliability Coordinators within the Eastern Interconnection when implementing transmission loading relief procedures (TLR) for the Eastern Interconnection to prevent or manage potential or actual System Operating Limit (SOL) and Interconnection Reliability Operating Limit (IROL) exceedances to maintain reliability of the Bulk Electric System (BES).
4. **Applicability:**
   - **4.1. Functional Entities:**
     - **4.1.1.** Reliability Coordinators in the Eastern Interconnection
5. **Effective Date:** See Implementation Plan for IRO-006-EAST-2.

B. Requirements and Measures

Rationale for recommendation to retire Requirement R1: The standard drafting team (IRO SDT) agrees with the FYRT's assertion that IRO-006-EAST-1 Requirement R1 is redundant with IRO-008-1, Requirement R3, and IRO-009-1, Requirement R4, and that the requirements in IRO-008-1 and IRO-009-1 are results based and specify a reliability objective to be achieved. The IRO SDT further agrees with the FYRT's conclusion that IRO-006-EAST-1 Requirement R1 simply provides a list of actions to be taken without any parameters for their use.
Rationale for recommendation to retire Requirement R3: The IRO SDT agrees with the FYRT's determination that the intent of Requirement R3 is not to define a curtailment process when the IDC is compromised or unavailable. In the event of an IDC failure, TLR action would be very limited resulting in manual curtailments and other manual actions to preserve the reliability of the Bulk Electric System. The IRO SDT further agrees with the FYRT's assertion that Requirement R3 contains actions that are automatically generated via the IDC tool and sent to proper entities upon issuance of the TLR. This requirement should be removed from the standard, as it meets Paragraph 81 Criterion B1 – Administrative.

Rationale for revisions to new Requirement R1 (previously Requirement R2): The IRO SDT provided edits to improve clarity and to incorporate and simplify the sub-requirements into the main requirement.

R1. Each Reliability Coordinator that initiates the Eastern Interconnection TLR procedure to prevent or mitigate an SOL or IROL exceedance shall identify the TLR level and the congestion management actions to be implemented, and shall update this information at least every clock hour (except TLR-1) after initiation up to and including the hour when the TLR level has been identified as TLR Level 0.[1] [*Violation Risk Factor: Medium*] [*Time Horizon: Real-time Operations*]

M1. Each Reliability Coordinator shall provide evidence (such as dated logs, voice recordings, or other information in electronic or hard-copy format) that at the time it initiated the Eastern Interconnection TLR procedure, and at least every clock hour after initiation up to and including the hour when the TLR level was identified as TLR Level 0, the Reliability Coordinator identified both the TLR Level and a list of congestion management actions to be implemented in accordance with Requirement R1.

Rationale for Revisions to new Requirement R2 (previously Requirement R4): The IRO SDT provided edits to improve clarity and to incorporate and simplify some of the bullets into the main requirement, and modified the remaining bullet to be a requirement instead of a passive statement.

R2. Each Reliability Coordinator with a Sink Balancing Authority that must implement congestion management actions pursuant to the Eastern Interconnection TLR procedure shall instruct the Sink Balancing Authority to implement the congestion management actions within 15 minutes of receiving the request from the issuing Reliability Coordinator, subject to the following exception: *[Violation Risk Factor: High] [Time Horizon: Real-time Operations]*

- Should an assessment determine that one or more of the congestion management actions communicated will result in a reliability concern or will be ineffective, the Reliability Coordinator with a Sink Balancing Authority shall coordinate alternate congestion management actions with the issuing Reliability Coordinator.

M2. Each Reliability Coordinator with a Sink Balancing Authority that must implement congestion management actions pursuant to the Eastern Interconnection TLR procedure shall provide evidence (such as dated logs, voice recordings, or other

[1] For more information on TLR levels, please see "Implementation Guideline for Reliability Coordinators: Eastern Interconnection TLR Levels Reference Document."

information in electronic or hard-copy format) that within fifteen minutes of the receipt of a request, the Reliability Coordinator complied with the request by either 1) instructing the Sink Balancing Authority to implement the congestion management actions requested by the issuing Reliability Coordinator, or 2) implementing none or some of the communicated congestion management actions requested by the issuing Reliability Coordinator, and replacing the remainder with alternate congestion management actions if assessment showed that some or all of the requested congestion management actions would have resulted in a reliability concern or would have been ineffective in accordance with Requirement R2.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:

"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1 and Requirement R2, the Reliability Coordinator shall maintain evidence to show compliance with Requirement R1 and Requirement R2 for the past 12 months plus the current month.

If a Reliability Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Enforcement Program

As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Additional Compliance Information

None.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for one clock hour during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for two clock hours during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for three clock hours during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.	The Reliability Coordinator initiating the Eastern Interconnection TLR procedure missed identifying the TLR Level and/or a list of congestion management actions to take as specified by the requirement for four or more clock hours during the period from initiation up to the hour when the TLR level was identified as TLR Level 0.
R2.				The responding Reliability Coordinator did not, within 15 minutes of receiving a request, either 1) instruct the Sink Balancing Authority to implement all the requested congestion management actions, or 2) coordinate alternate congestion management actions with the issuing Reliability Coordinator,

				provided that: assessment showed that the actions replaced would have resulted in a reliability concern or would have been ineffective.

D. Regional Variances

None.

IRO-009-2

Standards Involved

Approval:

- IRO-009-2 – Reliability Coordinator Actions to Operate within IROLs

Retirement:

- IRO-009-1 – Reliability Coordinator Actions to Operate within IROLs

Prerequisite Approvals

N/A

Background

Project 2015-06 Interconnection Reliability Operations and Coordination (Project) was initiated to implement the Project 2012-09 Interconnection Reliability Operations Five-Year Review Team (FYRT) recommendations to revise IRO-006-EAST-1 and IRO-009-1.

The FYRT originally reviewed IRO-003-2, IRO-004-2, IRO-005-4, IRO-006-5, IRO-006-East, IRO-008-1, IRO-009-1 and IRO-010-1a, and recommended revising all of these standards except for IRO-006-5, which was reaffirmed by the NERC Board of Trustees (Board). Additionally, Project 2014-03 Revisions to TOP and IRO Standards, retired IRO-003-2, IRO-004-2, IRO-005-4, IRO-008-1, and IRO-010-1a, leaving only IRO-006-EAST-1 and IRO-009-1 with outstanding recommendations for revision.

Based on the FYRT's recommendation to revise IRO-009-1 and industry comments in response to the 30-day informal comment period for the Project ending on April 15, 2015 the Project standard drafting team (SDT) recommends revising the standard as reflected in the posted documents.

General Considerations

Reliability Standard IRO-009-2 is proposed for approval to address the recommendations of the five-year review and industry comments.

Effective Date

Reliability Standard IRO-009-2 shall become effective on the first day of the first calendar quarter after the date that the standard is approved by an applicable governmental authority or as otherwise provided for in a jurisdiction where approval by an applicable governmental authority is required for a

standard to go into effect. Where approval by an applicable governmental authority is not required, the standard shall become effective the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Retirement of Existing Standards

Reliability Standard IRO-009-1 shall be retired at midnight of the day immediately prior to the effective date of IRO-009-2 in the particular jurisdiction in which the revised standard is becoming effective.

Implementation Plan

Reliability Standard IRO-009-1 will continue to be implemented pursuant to the Implementation Plan for IRO-009-1 and is incorporated herein by reference.

Cross References

The Implementation Plan for IRO-009-1 is available here.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Description of Current Draft

This version of Reliability Standard IRO-009 is posted for a 45-day concurrent comment and ballot period to address the recommendations of the Project 2012-09 Interconnected Reliability Operations Five-Year Review Team. That review resulted in a recommended drafting effort, which is being conducted by the Project 2015-06 Interconnection Reliability Operations and Coordination standard drafting team.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	March 11, 2015
SAR posted for comment	March 16 – April 15, 2015

Anticipated Actions	Anticipated Dates
45-day formal or informal comment period with ballot	May – July 2015
Final ballot	July 2015
NERC Board of Trustees (Board) adoption	November 2015

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s): None.

The rationale boxes will be moved to the Supplemental Material Section of the standard after the standard is adopted by the Board.

A. Introduction

1. **Title:** **Reliability Coordinator Actions to Operate Within IROLs**
2. **Number:** IRO-009-2
3. **Purpose:** To prevent instability, uncontrolled separation, or cascading outages that adversely impact the reliability of the interconnection by ensuring prompt action to prevent or mitigate instances of exceeding Interconnection Reliability Operating Limits (IROLs).
4. **Applicability:**

   4.1. Functional Entities:

   4.1.1. Reliability Coordinator.

5. **Effective Date:** See the Implementation Plan for IRO-009-2.

B. Requirements and Measures

Rationale for revisions to Requirement R1: The standard drafting team (IRO SDT) revised this requirement by combining IRO-009-1 Requirements R1 and R2 to form one requirement with two subparts to make the requirements more concise, as both requirements contained similar language.

R1. For each IROL (in its Reliability Coordinator Area) that the Reliability Coordinator identifies one or more days prior to the current day, the Reliability Coordinator shall have one or more Operating Processes, Procedures, or Plans that identify actions the Reliability Coordinator shall take or actions the Reliability Coordinator shall direct others to take (up to and including load shedding): *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning or Same Day Operations]*

1.1 That can be implemented in time to prevent the identified IROL exceedance.

1.2 To mitigate the magnitude and duration of an IROL exceedance such that the IROL is relieved within the IROL's T_V.

M1. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it has Operating Processes, Procedures, or Plans to address both preventing and mitigating the magnitude and duration of IROL exceedances in accordance with Requirement R1. This evidence shall include a list of any IROLs (and each associated Tv) identified in advance, along with one or more dated Operating Processes, Procedures, or Plans that that will be used.

Rationale for revisions to new Requirement R2 (previously Requirement R3): The IRO SDT revised the language of this requirement to improve clarity as well as consistency with similar NERC Board of Trustees (Board) approved standards, such as, TOP standard revisions (TOP-001-3 R14); "IROL exceedance," "Real Time monitoring," and "Real Time Assessments."

R2. Each Reliability Coordinator shall initiate one or more Operating Processes, Procedures, or Plans (not limited to the Operating Processes, Procedures, or Plans developed for Requirement R1) that are intended to prevent an IROL exceedance, as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment. *[Violation Risk Factor: High] [Time Horizon: Real-time Operations]*

M2. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it initiated one or more Operating Processes, Procedures or Plans (not limited to the Operating Processes, Procedures, or Plans developed for Requirements R1) in accordance with Requirement R2. This evidence could include, but is not limited to, Operating Processes, Procedures, or Plans from Requirement R1, dated operating logs, dated voice recordings, dated transcripts of voice recordings, or other evidence.

Rationale for Revisions to Requirement R3 (previously Requirement R4): The IRO SDT removed the term "without delay" from the requirement upon determining that the point of time at which the requirement is triggered is inherent in the requirement itself. The IRO SDT also revised the language of this requirement to improve clarity as well as consistency with similar Board approved standards, such as, TOP standard revisions (TOP-001-3 R14); "IROL exceedance," "Real Time monitoring," and "Real Time Assessments."

R3. Each Reliability Coordinator shall act or direct others to act so that the magnitude and duration of an IROL exceedance is mitigated within the IROL's Tv, as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment. *[Violation Risk Factor: High] [Time Horizon: Real-time Operations]*

M3. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it acted or directed others to act in accordance with Requirement R3. This evidence could include, but is not limited to, Operating Processes, Procedures, or Plans from Requirement R1, dated operating logs, dated voice recordings, dated transcripts of voice recordings, or other evidence.

Rationale for revisions to Requirement R4 (previously Requirement R5): The IRO SDT revised the language of this requirement for clarity as well as consistency with similar

Board approved standards, such as TOP standard revisions (TOP-001-3 R18). The IRO SDT retained clarifying language to limit applicability to appropriate affected RCs.

R4. Each Reliability Coordinator shall operate to the most limiting IROL and Tv in instances where there is a difference in an IROL or its Tv between Reliability Coordinators that are responsible for that Facility (or group of Facilities). *[Violation Risk Factor: High] [Time Horizon: Real-time Operations]*

M4. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it operated to the most limiting IROL and Tv in instances where there was a difference in an IROL or its Tv. Such evidence could include, but is not limited to, dated computer printouts, dated operator logs, dated voice recordings, dated transcripts of voice recordings, or other equivalent evidence in accordance with Requirement R4.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:

"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention:

The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Reliability Coordinator shall retain evidence of Requirement R1; Requirement R2; Requirement R3; and Requirement R4 for a rolling 12 months.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records, and all IROL Violation Reports submitted since the last audit.

1.3. Compliance Monitoring and Enforcement Program

As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Additional Compliance Information

Exception Reporting: For each instance of exceeding an IROL for time greater than IROL Tv, the Reliability Coordinator shall submit an IROL Violation Report to its Compliance Enforcement Authority within 30 days of the initiation of the event.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.				An IROL in its Reliability Coordinator Area was identified one or more days in advance and the Reliability Coordinator does not have an Operating Process, Procedure, or Plan that identifies actions to prevent that IROL exceedance (Part 1.1). OR An IROL in its Reliability Coordinator Area was identified one or more days in advance and the Reliability Coordinator does not have an Operating Process, Procedure, or Plan that identifies actions to mitigate that IROL exceedance within the IROL's T_V. (Part 1.2).
R2.				No Operating Processes, Procedures, or Plans were

				initiated that were intended to prevent a predicted IROL exceedance as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment.
R3.				Actual system conditions showed that there was an IROL exceedance in its Reliability Coordinator Area, and that the IROL exceedance was not mitigated within the IROL's Tv.
R4.				The most limiting IROL or its Tv was not operated to between Reliability Coordinators that are responsible for the Facility (or group of Facilities) associated with the IROL.

Anticipated Actions	Anticipated Dates
45-day formal or informal comment period with ballot	May – July 2015
Final ballot	July 2015
NERC Board of Trustees (Board) adoption	November 2015

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s): **None.**

The rationale boxes will be moved to the Supplemental Material Section of the standard after the standard is adopted by the Board.

A. Introduction

1. **Title:** **Reliability Coordinator Actions to Operate Within IROLs**

2. **Number:** IRO-009-~~1~~2

3. **Purpose:** To prevent instability, uncontrolled separation, or cascading outages that adversely impact the reliability of the interconnection by ensuring prompt action to prevent or mitigate instances of exceeding Interconnection Reliability Operating Limits (IROLs).

4. **Applicability:**

   4.1. Reliability Coordinator.

5. ~~**Proposed**~~ **Effective Date:**
   ~~In those jurisdictions where no regulatory approval is required, the standard shall become effective on the latter of either April 1, 2009 or the first day of the first calendar quarter, three months after BOT adoption.~~

   ~~In those jurisdictions where regulatory approval is required, the standard shall become effective on the latter of either April 1, 2009 or the first day of the first calendar quarter, three months after applicable regulatory approval.~~See the Implementation Plan for IRO-009-2.

B. Requirements

Rationale for revisions to Requirements R1: The standard drafting team (IRO SDT) revised this requirement by combining IRO-009-1 Requirements R1 and R2 to form one requirement with two subparts to make the requirements more concise, as both requirements contained similar language.

R1. For each IROL (in its Reliability Coordinator Area) that the Reliability Coordinator identifies one or more days prior to the current day, the Reliability Coordinator shall have one or more Operating Processes, Procedures, or Plans that identify actions ~~it~~ the Reliability Coordinator shall take or actions ~~it~~ the Reliability Coordinator shall direct others to take (up to and including load shedding): ~~that can be implemented in time to prevent exceeding those IROLs.~~ *(Violation Risk Factor: Medium) (Time Horizon: Operations Planning or Same Day Operations)*

~~1.1~~ That can be implemented in time to prevent the identified IROL exceedance.

1.1

1.2 ~~**R2.** For each IROL (in its Reliability Coordinator Area) that the Reliability Coordinator identifies one or more days prior to the current day, the Reliability Coordinator shall have one or more Operating Processes, Procedures, or Plans that identify actions it shall take or actions it shall direct others to take (up to and including load shedding) t~~To mitigate the magnitude and duration of ~~exceeding an~~that ~~IROL~~ IROL exceedance such that the IROL is relieved within the IROL's

Tv. *(Violation Risk Factor: Medium) (Time Horizon: Operations Planning or Same Day Operations)*

Rationale for revisions to new Requirement R2 (previously Requirement R3): The IRO SDT revised the language of this requirement to improve clarity as well as consistency with similar NERC Board of Trustees (Board) approved standards, such as, TOP standard revisions (TOP-001-3 R14); "IROL exceedance," "Real Time monitoring," and "Real Time Assessments."

R23. When an assessment of actual or expected system conditions predicts that an IROL in its Reliability Coordinator Area will be exceeded, the Each Reliability Coordinator shall implement initiate one or more Operating Processes, Procedures, or Plans (not limited to the Operating Processes, Procedures, or Plans developed for Requirements R1) that are intended to prevent exceeding that an IROL exceedance as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment.. *(Violation Risk Factor: High) (Time Horizon: Real-time – Operations)*

Rationale for revisions to new Requirement R3 (previously Requirement R4): The IRO SDT removed the term "without delay" from the requirement upon determining that the point of time at which the requirement is triggered is inherent in the requirement itself. The IRO SDT also revised the language of this requirement to improve clarity as well as consistency with similar Board approved standards, such as, TOP standard revisions (TOP-001-3 R14); "IROL exceedance," "Real Time monitoring," and "Real Time Assessments."

R4R3. When actual system conditions show that there is an instance of exceeding an IROL in its Reliability Coordinator Area, the Each Reliability Coordinator shall, without delay, act or direct others to act so that to mitigate the magnitude and duration of the instance of exceeding that an IROL exceedance is mitigated within the IROL's Tv, identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment. *(Violation Risk Factor: High) (Time Horizon: Real-time Operations)*

Rationale for revisions to Requirement R4 (previously Requirement R5): The IRO SDT revised the language of this requirement for clarity as well as consistency with similar Board approved standards, such as TOP standard revisions (TOP-001-3 R18). The IRO SDT retained clarifying language to limit applicability to appropriate affected RCs.

R45. ~~If unanimity cannot be reached on the value for an IROL or its Tv, e~~Each Reliability Coordinator ~~that monitors that Facility (or group of Facilities)~~ shall operate to~~, without delay, use~~ the most limiting IROL and Tv in instances where there is a difference in an IROL or its Tv between Reliability Coordinators that are responsible for that Facility (or group of Facilities).~~conservative of the values (the value with the least impact on reliability) under consideration.~~ *(Violation Risk Factor: High) (Time Horizon: Real-time Operations)*

C. Measures

M1. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it has Operating Processes, Procedures, or Plans to address both preventing and mitigating the magnitude and duration of IROL exceedances ~~instances of exceeding IROLs~~ in accordance with Requirement R1 ~~and Requirement R2~~. This evidence shall include a list of any IROLs (and each associated Tv) identified in advance, along with one or more dated Operating Processes, Procedures, or Plans that that will be used.

M2. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it initiated one or more Operating Processes, Procedures or Plans (not limited to the Operating Processes, Procedures, or Plans developed for Requirements R1) in accordance with Requirement R2. This evidence could include, but is not limited to, Operating Processes, Procedures, or Plans from Requirement R1, dated operating logs, dated voice recordings, dated transcripts of voice recordings, or other evidence.

M3. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it acted or directed others to act in accordance with Requirement R3. This evidence could include, but is not limited to, Operating Processes, Procedures, or Plans from Requirement R1, dated operating logs, dated voice recordings, dated transcripts of voice recordings, or other evidence.~~M2. Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it acted or directed others to act in accordance with Requirement R3 and Requirement R4. This evidence could include, but is not limited to, Operating Processes, Procedures, or Plans from Requirement R1, dated operating logs, dated voice recordings, dated transcripts of voice recordings, or other evidence.~~

M43. ~~For a situation where Reliability Coordinators disagree on the value of an IROL or its Tv, the~~Each Reliability Coordinator shall have, and make available upon request, evidence to confirm that it operated to the most limiting IROL and Tv in instances where there was a difference in an IROL or its Tv~~used the most conservative of the values under consideration, without delay.~~ Such evidence could include, but is not limited to, dated computer printouts, dated operator logs, dated voice recordings, dated transcripts of voice recordings, or other equivalent evidence in accordance with Requirement R4. ~~(R5)~~

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority:

"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

~~For Reliability Coordinators that work for the Regional Entity, the ERO shall serve as the Compliance Enforcement Authority.~~

~~For Reliability Coordinators that do not work for the Regional Entity, the Regional Entity shall serve as the Compliance Enforcement Authority.~~

1.1. Evidence Retention:

The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Reliability Coordinator shall retain evidence of Requirement R1; Requirement R2; Requirement R3; and Requirement for a rolling 12 months.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records, and all IROL Violation Reports submitted since the last audit.

1.2. Compliance Monitoring and Enforcement Program

As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.3. Additional Compliance Information

Exception Reporting: For each instance of exceeding an IROL for time greater than IROL Tv, the Reliability Coordinator shall submit an IROL Violation Report to its Compliance Enforcement Authority within 30 days of the initiation of the event.

~~**1.2. Compliance Monitoring Period and Reset Time Frame**~~

~~Not applicable.~~

~~**1.3. Compliance Monitoring and Enforcement Processes**~~

~~Compliance Audits~~

~~Self-Certifications~~

~~Spot Checking~~

~~Compliance Violation Investigations~~

~~Self-Reporting~~

~~Complaints~~

Exception Reporting

1.4. Data Retention

The Reliability Coordinator, shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

The Reliability Coordinator shall retain evidence of Requirement R1, Requirement R2, and Measure M1, for a rolling 12 months.

The Reliability Coordinator shall retain evidence of Requirement R3, Requirement R4, Requirement R5, Measure M2, and Measure M3 for a rolling 12 months.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records, and all IROL Violation Reports submitted since the last audit.

1.5. Additional Compliance Information

Exception Reporting: For each instance of exceeding an IROL for time greater than IROL T_V, the Reliability Coordinator shall submit an IROL Violation Report to its Compliance Enforcement Authority within 30 days of the initiation of the event.

2. Violation Severity Levels

Requirement	Lower	Moderate	High	Severe
R1				An IROL in its Reliability Coordinator Area was identified one or more days in advance and the Reliability Coordinator does not have an Operating Process, Procedure, or Plan that identifies actions to prevent that IROL exceedance (Part 1.1). OR An IROL in its Reliability Coordinator Area was identified one or more days in advance and the Reliability Coordinator does not have an Operating Process, Procedure, or Plan that identifies actions to mitigate that IROL exceedance within the IROL's Tv. (Part 1.2)~~An IROL in its Reliability Coordinator Area was identified one or more days in advance and the~~

~~R2~~				~~An IROL in its Reliability Coordinator Area was identified one or more days in advance and the Reliability Coordinator does not have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv. (R2)~~
R23				~~An assessment of actual or expected system conditions predicted that an IROL in the Reliability Coordinator's Area would be exceeded, but n~~No Operating Processes, Procedures, or Plans were ~~implemented~~ initiated that were intended to prevent a predicted IROL exceedance as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment. ~~(R3)~~

R~~3~~4			~~Actual system conditionsshowed that there was an instance of exceeding an IROL in its Reliability Coordinator Area, and there was a delay of five minutes or more before acting or directing others to act to mitigate the magnitude and duration of the instance of exceeding that IROL, however the IROL was mitigated within the IROL Tv.~~	Actual system conditions showed that there was an IROL exceedance in its Reliability Coordinator Area, and that the IROL exceedance was not ~~resolved~~mitigated within the IROL's Tv.

Requirement	Lower	Moderate	High	Severe
			showed that there was an instance of exceeding an IROL in its Reliability Coordinator Area, and there was a delay of five minutes or more before acting or directing others to act to mitigate the magnitude and duration of the instance of exceeding that IROL, however the IROL was mitigated within the IROL Tv. (R4)	showed that there was an instance of exceeding an IROL in its Reliability Coordinator Area, and that IROL was not resolved within the IROL's Tv. (R4)
R45	Not applicable.	Not applicable.	Not applicable.	The most limiting IROL or its TV was not operated to between Reliability Coordinators that are responsible for the Facility (or group of Facilities) associated with the IROL.There was a disagreement on the value of the IROL or its Tv and the most conservative limit under consideration was not used. (R5)

Violation Risk Factor and Violation Severity Level Justifications

Project 2015-06 Interconnection Reliability Operations and Coordination
IRO-006-EAST-2, IRO-009-2

Violation Risk Factor and Violation Severity Level Justifications

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in IRO-006-EAST-2 (Transmission Loading Relief Procedure for the Eastern Interconnection) and IRO-009-2 (Reliability Coordinator Actions to Operate within IROLs).

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

The Interconnection Reliability Operations and Coordination Standard Drafting Team applied the following NERC criteria and FERC Guidelines when proposing VRFs and VSLs for the requirements under this project:

NERC Criteria – VRFs

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to

effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

FERC VRF Guidelines

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) — Consistency among Reliability Standards
The Commission expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the VRF Level
Guideline 4 was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

Consideration of FERC VRF Guidelines

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

IRO-006-EAST-2

Reliability Standard IRO-006-EAST-2 is a revision of IRO-006-EAST-1 TLR Procedure for the Eastern Interconnection, with the following stated purpose: "To ensure coordinated action between Reliability Coordinators within the Eastern Interconnection when implementing transmission loading relief procedures (TLR) for the Eastern Interconnection to prevent or manage potential or actual System Operating Limit (SOL) and Interconnection Reliability Operating Limit (IROL) exceedances to maintain reliability of the Bulk Electric System (BES)."

Reliability Standard IRO-006-EAST-2 has two (2) requirements that address identification of TLR level(s) and identification and instruction to implement congestion management actions. The requirements originated from revisions to two (2) requirements that existed in Reliability Standard IRO-006-EAST-1, Requirement R2 and Requirement R4. Reliability Standard IRO-006-EAST-2 seeks to retire two (2) other requirements that existed in IRO-006-EAST-1, Requirement R1 and Requirement R3. As such, the VRFs and VSLs associated with IRO-006-EAST-1, Requirement R1 and Requirement R3 have not been included in IRO-006-EAST-2.

Reliability Standard IRO-006-EAST-2 Requirement R1 maps to IRO-006-EAST-1 Requirement R2, and IRO-006-EAST-2 Requirement R2 maps to IRO-006-EAST-1 Requirement R4. The drafting team did not revise the VRFs for the requirements of IRO-006-EAST-2 Requirement R1 or Requirement R2.

The drafting team revised the VSL for IRO-006-EAST-2 Requirement R2 to conform to the revisions to the language of IRO-006-EAST-2 Requirement R2.

IRO-009-2

Reliability Standard IRO-009-2 is a revision of IRO-009-1 Reliability Coordinator Actions to Operate Within IROLs, with the following stated purpose: To prevent instability, uncontrolled separation, or cascading outages that adversely impact the reliability of the interconnection by ensuring prompt action to prevent or mitigate instances of exceeding Interconnection Reliability Operating Limits (IROLs).

Reliability Standard IRO-009-2 has four (4) requirements that address Reliability Coordinator Operating Process, Procedure, or Plans that identify actions the Reliability Coordinator shall take or actions the Reliability Coordinator shall direct others to take to prevent exceeding that IROL, that can be implemented in time to prevent exceeding the identified IROL, mitigate exceeding that IROL within the IROL's Tv, Operating Processes, Procedures or Plans to prevent an IROL exceedance as part of its Real-time monitoring or Real-time Assessment, acts the Reliability Coordinator shall take or direct others to take so that the magnitude and duration of an IROL exceedance is mitigated within the IROL's Tv as part of its Real-time monitoring or Real-time Assessment, and Reliability Coordinator operation to the most limiting IROL and Tv in instances where there is a difference in an IROL or its Tv between Reliability Coordinators that are responsible for a Facility (or group of Facilities). The requirements originated from revisions to the five (5) requirements that existed in IRO-009-1, Requirement R1 through Requirement R5. Reliability Standard IRO-009-2 seeks to revise Requirement R1 and R2 by incorporating the requirements from Requirement R2 into Requirement R1 as Part R1.1 and R1.2.

The IRO-009-2 Requirement R1 maps to IRO-009-1 Requirement R1 and Requirement R2. The VRFs for IRO-009-1 Requirement R1 and Requirement R2 were both medium, therefore, the drafting team did not revise the VRFs for the requirements when revising IRO-009-2 Requirement R1 to include IRO-009-1 Requirement R2.

Reliability Standard IRO-009-2 Requirement R2 maps to IRO-009-1 Requirement R3; IRO-009-2 Requirement R3 maps to IRO-009-1 Requirement R4; IRO-009-2 Requirement R4 maps to IRO-009-1 Requirement R5. The drafting team did not revise the VRFs for the requirements of IRO-006-EAST-1 Requirement R3, Requirement R4, or Requirement R5.

The drafting team revised the VSLs for IRO-009-2 Requirements R2 through R4 to conform to the revisions to the language of IRO-009-2 Requirements R2 through R4.

NERC Criteria - VSLs

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one (1) VSL. While it is preferable to have four (4) VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one (1), two (2), or three (3) VSLs.

VSLs should be based on the guidelines shown in the table below:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital Component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC Order on VSLs

In its June 19, 2008 Order[1] on VSLs, FERC indicated it would use the following four guidelines for determining whether to approve VSLs:

Guideline 1: VSL Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

- Compare the VSLs to any prior Levels of Non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when Levels of Non-compliance were used.

Guideline 2: VSL Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

- Guideline 2a: A violation of a "binary" type requirement must be a "Severe" VSL.
- Guideline 2b: Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: VSL Assignment Should Be Consistent with the Corresponding Requirement

- VSLs should not expand on what is required in the requirement.

Guideline 4: VSL Assignment Should Be Based on a Single Violation, Not on a Cumulative Number of Violations

- . . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

[1] *Order on Violation Severity levels Proposed by the Electric Reliability Organization*, 123 FERC ¶61,284 (2008)

VRF and VSL Justifications

VRF and VSL Justifications – IRO-006-EAST-2, R2			
Proposed VSL – IRO-006-EAST-2, R2			
Lower	**Moderate**	**High**	**Severe**
			The responding Reliability Coordinator did not, within 15 minutes of receiving a request, either 1) instruct the Sink Balancing Authority to implement all the requested congestion management actions, or 2) coordinate alternate congestion management actions with the issuing Reliability Coordinator, provided that: assessment showed that the actions replaced would have resulted in a reliability concern or would have been ineffective.
FERC VSL G3 VSL Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.		
FERC VSL G4	The VSL is based on a single violation and not cumulative violations.		

VRF and VSL Justifications – IRO-006-EAST-2, R2	
Proposed VSL – IRO-006-EAST-2, R2	
VSL Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	

VRF and VSL Justifications – IRO-009-2, R1	
Proposed VRF – IRO-009-2, R1	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to have an Operating Process, Procedure, or Plan that identifies actions to prevent exceeding that IROL and failure to have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from failure to have an Operating Process, Procedure, or Plan that identifies actions to prevent exceeding that IROL and failure to have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv. Failure to have an Operating Process, Procedure, or Plan that identifies actions to prevent exceeding that IROL and failure to have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv will not, by themselves, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no sub-requirements so only one VRF was assigned. The requirement utilizes Parts to identify the items to be included within the requirement. The VRF for this requirement is consistent with others in the standard with regard to relative risk; therefore, there is no conflict.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards:

VRF and VSL Justifications – IRO-009-2, R1	
Proposed VRF – IRO-009-2, R1	
	Since the SDT revised the requirement to include a requirement that was already approved along with its associated VRF and VSL, the SDT concludes that there is consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a Medium VRF, which is consistent with the VRF that this requirement and the requirement that was combined with this requirement were previously assigned in the approved standard.

VRF and VSL Justifications – IRO-009-2, R1			
Proposed VRF – IRO-009-2, R1			
Proposed VRF	**Medium**		
FERC VRF G4 Discussion	Failure to have an Operating Process, Procedure, or Plan that identifies actions to prevent exceeding that IROL and failure to have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from failure to have an Operating Process, Procedure, or Plan that identifies actions to prevent exceeding that IROL and failure to have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv. Failure to have an Operating Process, Procedure, or Plan that identifies actions to prevent exceeding that IROL and failure to have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv will not, by themselves, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.		
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.		
Proposed VSL – IRO-009-2, R1			
Lower	**Moderate**	**High**	**Severe**
			An IROL in its Reliability Coordinator Area was identified one or more days in advance and the Reliability Coordinator does not have an Operating Process, Procedure, or Plan that identifies actions to

			prevent exceeding that IROL (Part 1.1). OR An IROL in its Reliability Coordinator Area was identified one or more days in advance and the Reliability Coordinator does not have an Operating Process, Procedure, or Plan that identifies actions to mitigate exceeding that IROL within the IROL's Tv. (Part 1.2)

VRF and VSL Justifications – IRO-009-2, R1	
Proposed VSL – IRO-009-2, R1	
FERC VSL G3 VSL Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 VSL Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – IRO-009-2, R2			
Proposed VSL – IRO-009-2, R2			
Lower	**Moderate**	**High**	**Severe**
			No Operating Processes, Procedures, or Plans were initiated that were intended to prevent a predicted IROL exceedance as identified in the Reliability Coordinator's Real-time monitoring or Real-time Assessment.

Proposed VSL – IRO-009-2, R4	
VSL Assignment Should Be Consistent with the Corresponding Requirement	
FERC VSL G4 VSL Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Proposed Revisions to Align Definitions in the Glossary of Terms and Rules of Procedure

Project 2015-04 – Alignment of Terms

Part I. Executive Summary

Currently there are fifty-five (55) defined terms that appear in both the NERC Glossary of Terms Used in Reliability Standards (Glossary) and Rules of Procedure (ROP) ("cross-over terms"), a complete list of which can be found in Attachment 1. Of the fifty-five (55) cross-over terms, forty (40) contain inconsistencies or differences in the definition narratives, which causes industry confusion and may lead to inconsistent interpretation or application of the meaning of a term. Consistency between the defined terms in the Glossary and the ROP will enhance reliability by providing the owners, users and operators of the BES, as well as the ERO Enterprise, with a better understanding of the terminology used in the Glossary and the ROP. To achieve this consistency, the SDT is proposing alignment revisions to twenty-six (26) Glossary terms and sixteen (16) ROP terms.

This document provides an overview of the work undertaken by the Project 2015-04 standard drafting team (SDT) to align the cross-over terms and the revisions proposed by the SDT. Part II provides an overview of the purpose, scope and substance of the work undertaken by the SDT during this project. Parts III through VI provide the background information and research conducted by the SDT for each cross-over term under revision, and an analysis and justification to support the revisions being proposed by the team to align the terms.

Part II. Project Overview and Background Information

Background information regarding the Glossary and ROP

In 2007, when FERC approved Version 0 of the Reliability Standards, it also approved the NERC Glossary of Terms. (*See*, FERC Order No. 693). In Order No. 693, FERC noted the importance of the defined terms in establishing a consistent understanding of the Reliability Standards Requirements and implementation. (*See*, FERC Order No. 693 at P 1893). The NERC Glossary provides continuity in the application of the glossary definitions industry-wide and eliminates multiple interpretations of the same term or function, which could otherwise create miscommunication or jeopardize reliability. Similarly, FERC approved the Rules of Procedure, which contained a number of FERC-approved defined terms. Later, in 2011, at FERC's suggestion, NERC petitioned to move all of the defined terms contained in the various sections and Appendices of the ROP into one central location, Appendix 2 to the ROP. The definitions included in Appendix 2 were "taken largely from existing sources, including Section 215 of the Federal Power Act; the Commission's regulations; the NERC Bylaws, the NERC Glossary of Terms Used in Reliability Standards; and existing definitions found in the ROP and Appendices…" (*See*, NERC Petition, p. 8). Those definitions taken

from the Glossary were marked with a double asterisk (**), while definitions taken from the Federal Power Act were marked with a double plus sign (++).

Following FERC's approval of the Glossary and Appendix 2 to the ROP, there have been a number of necessary revisions to the defined terms contained therein. Glossary terms are revised through the Reliability Standards development process; whereas ROP terms are revised through the ROP revision process. (*See*, NERC Rules of Procedure, Appendix 3A: Standards Process Manual and ROP, Section 1400). As a result of various changes made to defined terms over the years through these distinct revision processes, a number of cross-over terms, which were once identical, now contain differences in their definition narratives. As outlined in the SAR for this project, the purpose of this project is to align the defined terms found in the Glossary and the ROP. Additionally, the SDT will also develop recommendations regarding how to enhance the current definition development processes in the Standards Process Manual and ROP to prevent misalignment or inconsistencies during future development of defined terms.

Work undertaken by the Project 2015-04 SDT

First, the SDT identified all existing defined terms that are contained in both the Glossary and the ROP ("cross-over terms"), a complete list of which can be found in Attachment 1. From this complete list of cross-over terms, the team then identified those cross-over terms that contained definitional differences. After analyzing these definitional differences, the SDT identified common alignment issues and categorized the terms into different "groups" based upon the type of alignment issue identified. Below is a summary of each grouping:

Group 1: Group 1 cross-over terms contain differences in the substance or content of the definition. In some instances, the differences resulted in the defined terms having different meanings or application. For example, the definitions for "Net Energy for Load" are substantively different in the Glossary and ROP because they are used differently in the respective documents. In other instances, although the content or language of the definition was different, the end result or application of the definition was, nevertheless, the same. For example, the term "Adjacent Balancing Authority" is defined differently in the Glossary than the ROP, with the Glossary definition providing greater clarity. There are a total of nine (9) Group 1 cross-over terms, and the SDT is proposing alignment revisions to eight (8) of those terms.

Group 2: Group 2 cross-over terms are similar to Group 1 terms in that the definitions contain substantive differences in the definitions. However, these terms are grouped separately because they are currently under revision, not yet approved by the NERC Board of Trustees, or pending regulatory approval. There are six (6) Group 2 cross-over terms in total, and at this time, the SDT is recommending alignment revisions to one (1) of those terms. The SDT has, however, made recommendations for future action to address a number of the remaining Group 2 cross-over terms.

Group 3: Group 3 cross-over terms contain differences in the capitalization of terms that are included in the definition narrative, but are otherwise aligned in substance and content. Since capitalization of a term indicates that it is a defined term with a specific meaning, these inconsistencies in capitalization cause confusion and may lead to inconsistent application of the definition. For example, the definition narrative of "Interconnected Operations Services" is the same in the Glossary and ROP; however, the ROP

narrative capitalizes “Transmission Services” and “Reliable Operation,” while the Glossary does not. There are a total of twenty-two (22) Group 3 cross-over terms, and the SDT is recommending alignment revisions to all of those terms.

Group 4: Group 4 cross-over terms contain errata-type differences, such as the inadvertent omission of a word or letter. There are three (3) Group 4 cross-over terms in total, and the SDT is proposing alignment revisions to all of those terms.

Below is a detailed summary of the SDT’s recommendations for each of the cross-over terms, organized by Group. Also, Attachment 2 contains a summary of all alignment revisions proposed by the SDT.

The SDT undertook substantial background research before determining whether alignment revisions were appropriate for each of the cross-over terms under consideration, including an examination of the history of the term’s definition, previous drafting teams’ intent, relevant NERC filings to FERC, and any FERC orders approving the term’s definition. Additionally, the SDT examined how each term is used in the Glossary, Reliability Standards, and ROP provisions. Based on this thorough examination, the SDT determined whether revisions were appropriate. In some instances, the SDT concluded that alignment revisions were not appropriate due to differing application of the terms in the Glossary and/or ROP. Also, for a number of terms, the SDT identified areas where the definition language could be improved, given industry usage. For such terms, the SDT will develop a Standards Authorization Request (SAR) outlining the identified issues, and the team’s proposal for how to address each issue. Of the fifty-five (55) cross-over terms, forty (40) contain inconsistencies or differences in the definition narratives. To achieve consistency and alignment of these cross-over terms, the SDT is proposing revisions to twenty-six (26) Glossary terms and sixteen (16) ROP terms.

Part III: Group 1 recommendations

There are a total of nine (9) Group 1 cross-over terms:

Term 1: Adjacent Balancing Authority

Term 6: Bulk Power System

Term 17: Generator Operator

Term 18: Generator Owner

Term 29: Net Energy for Load or NEL

Term 40: Reliability Standard

Term 44: Sink Balancing Authority

Term 45: Source Balancing Authority

Term 48: System Operating Limit

The SDT is recommending revisions to eight (8) of the Group 1 cross-over terms. Below is an overview of the SDT research, assessment, proposed revision(s), and justification for each of the recommendations.

Term 1: Adjacent Balancing Authority

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
A Balancing Authority whose Balancing Authority Area is interconnected with another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.	a Balancing Authority Area that is interconnected to another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**	The SDT is proposing to revise the ROP definition to align with the Glossary. Redline of ROP definition: a Balancing Authority ~~Area~~ whose Balancing Authority Area ~~that~~ is interconnected with ~~to~~ another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**

I. HISTORY AND BACKGROUND INFORMATION REGARDING "ADJACENT BALANCING AUTHORITY" DEFINITION

History of Glossary term:

- Previous version(s): Effective dates: 3/16/2007 – 09/30/2014 ("A Balancing Authority Area that is interconnected another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.")
- Current version: **Effective as of 10/01/2014**
  - Revised by Project 2008-12 Coordinate Interchange Standards
  - NERC Petition (02/27/2014) - "The proposed revisions are minor, non-substantive changes to improve the clarity of the term, as illustrated in Exhibit F. The proposed revisions are intended to clarify the various Balancing Authorities involved in the implementation of Interchange and their relationships with regards to Interchange." (p. 29)
  - FERC Order (06/30/2014) – FERC letter order approving revised Glossary definition

History of ROP term:

- Current version: **Effective as of 01/31/2012**
  - NERC Petition (11/29/2011) - Added Appendix 2 to ROP and adopted existing Glossary definition for Adjacent Balancing Authority. (see p. 9)
  - FERC Order (01/31/2012) - "These revisions are being proposed as a result of P 93 of the Commission's Order issued October 21, 2010, in Docket No. RR10-11-000, in which the Commission invited NERC to submit a filing making consistent use of defined terms throughout the ROP and Appendices." (p. 1)

II. USAGE OF DEFINED TERM: ADJACENT BALANCING AUTHORITY

List of usage of the term Adjacent Balancing Authority within Reliability Standards:

	Reliability Standard
1	BAL-001-2
2	BAL-002-1a
3	BAL-005-0.2
4	BAL-006-2
5	COM-001-2
6	EOP-001-2.1b

7	INT-009-2.1
8	MOD-028-2
9	MOD-030-2
10	MOD-030-3

List of ROP provisions (other than Appendix 2) where Adjacent Balancing Authority occurs:

	ROP provision	Page # [Link to ROP]
1	Appendix 5B – Functional type definition under Section II: Reserve Sharing Group	435 of 483

List defined terms that include Adjacent Balancing Authority in definition narrative:

	Glossary
1	Net Actual Interchange
2	Net Interchange Schedule
3	Reserve Sharing Group

	ROP
1	N/A
2	N/A
3	Reserve Sharing Group

List of other defined terms that are included in the Adjacent Balancing Authority definition narrative:

Glossary: Balancing Authority Area, Balancing Authority
ROP: Balancing Authority Area

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The differences in definition narratives are minor and non-substantive in nature. The Glossary definition clarifies the various Balancing Authorities involved in the implementation of the Interchange and their respective relationships with Interchange.

How/why the terms may be applied differently as a result of the differences: The language added through the Project 2008-12 Coordinate Interchange Standards did not impact the definitions. A review of the ROP and Reliability Standards containing the defined term was conducted, and the differences do not result in different application of the term. The Glossary definition simply provides greater clarity.

Proposed revision(s): The SDT proposes to revise the ROP definition to align with the Glossary. No changes are proposed to the Glossary definition.

Redline of ROP definition:

a Balancing Authority ~~Area~~ whose Balancing Authority Area ~~that~~ is interconnected with ~~to~~ another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**

Justification for decision: The ROP definition adopted the Glossary definition when Appendix 2 was created in 2012. Note that the ROP definition is marked with a double asterisk (**), indicating it was taken from the Glossary. Subsequently, in 2014, the Glossary term was revised to provide greater clarity. The revised Glossary definition clarifies the various Balancing Authorities involved in the implementation of Interchange and their relationships with regard to Interchange. The ROP definition was not updated to reflect the clarifying revisions made to the Glossary definition.

Term 6: Bulk Power System

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
Bulk-Power System: A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.	Bulk Power System" means, depending on the context: (i) Facilities and control systems necessary for operating an interconnected electric energy supply and transmission network (or any portion thereof), and electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy [++]. (ii) Solely for purposes of Appendix 4E, Bulk Electric System.	The SDT is proposing to revise both definitions as follows: Redline of Glossary definition: Bulk- Power System: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.) Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning. Redline of ROP, Appendix 2 definition: Bulk Power System" means, depending on the context: (i) (A) ~~Facilities~~ facilities and control systems necessary for operating an interconnected electric energy ~~supply and~~ transmission network (or any portion thereof);~~,~~ and (B) electric energy from generation~~g~~ facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. [++] (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.)~~-~~Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning. (ii) Solely for purposes of Appendix 4E, Bulk Electric System.

I. HISTORY AND BACKGROUND INFORMATION REGARDING BULK POWER SYSTEM DEFINITION

History of Glossary term:

- Original version: Effective through 07/08/13
  - FERC Order No. 693 (03/16/07): "The Commission directs the ERO to modify the glossary through the Reliability Standards development process to include the statutory definitions of the terms Bulk-Power System, Reliable Operation and Reliability Standard. However, this determination does not negate our discussion in the Applicability section of the Final Rule. While the glossary should be revised to include the statutory definition of Bulk-Power System, the Reliability Standards refer to the bulk electric system, which is also defined in the glossary." (P 1894)

- Current version: **Effective as of 07/09/13**
  - Revised by Project 2012-08.1 Phase 1 of the Glossary Updates for Statutory Definitions
  - NERC Petition (05/10/13):

    "The term "Bulk-Power System" is defined in section 215 of the FPA as follows:

    (1) The term 'bulk-power system' means—

    (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and

    (B) electric energy from generation facilities needed to maintain transmission system reliability.

    The term does not include facilities used in the local distribution of electric energy.

    The proposed definition of the term "Bulk-Power System" for inclusion in the NERC Glossary is as follows: "Bulk-Power System" means, (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. The proposed definition of "Bulk-Power System" is identical to the definition in section 215 of the FPA and should therefore be accepted in compliance with the Commission's directive in Order No. 693." (pp. 5-6)
  - FERC Order (07/9/13) - Letter order approving proposed definitions

History of ROP term:

- Original version:
  - ERO Application (04/04/06) – NERC Bylaws: "Bulk power system" means facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof) and electric energy from generation facilities needed to maintain transmission system reliability, but does not include facilities used in the local distribution of electricity.
  - FERC Order (07/20/06) - 'We direct NERC to adopt definitions of the terms defined in Order No. 672 throughout its documents in its compliance filing. Any other definition of those terms is not acceptable.' (P 727)

- Revised version:
  - NERC Compliance Filing Addressing Governance Issues (09/18/2006): "NERC has modified the definitions of 'bulk power system', 'electric reliability organization', and 'regional entity' in Article I, Section 1 of the Bylaws to track the definitions in Order No. 672. NERC will also track the Order No. 672 definitions in its Rules of Procedure…"
  - NERC Non-Governance Compliance Filing (10/18/06): "NERC has modified the definitions of 'bulk power system', 'electric reliability organization', and 'regional entity' in Article I, Section 1 of its Bylaws to track the definitions in Order No. 672. NERC has also revised definitions in its Rules of Procedure to match definitions in Section 215(a) of the Federal Power Act and/or Part 39 of the Commission's regulations, including 'bulk power system', 'electric reliability organization,' 'reliable operation,' and 'reliability standard'." (pp. 71-72)

    "Bulk power system" means facilities and control systems necessary for operating an interconnected electric energy supply and transmission network (or any portion thereof), and electric energy from generating facilities needed to maintain transmission system

reliability. The term does not include facilities used in the local distribution of electric energy. (Attachment 1, Revised ROP, at Section 202 Specific Definitions)

- FERC Order Accepting Governance Compliance Filing (10/30/06): "NERC has modified the definitions of 'Bulk-Power System,' 'Electric Reliability Organization,' and 'Regional Entity' in article I, section 1 of the Bylaws to track the definitions in Order No. 672. NERC states that it also intends to incorporate Order No. 672 definitions in its Rules of Procedure." (P 125)
- FERC Order Accepting Non-Governance Compliance Filing (01/18/07): "NERC has appropriately revised definitions in its Bylaws and its Rules of Procedure to reflect these same definitions in Order No. 672." (P 223)

- Current version: **Effective as of 01/31/2012**
  - NERC Petition to Revise ROP (11/29/11): "The purposes of the proposed revisions are (1) to place all definitions of defined terms used anywhere in the ROP in a single, readily-accessible location (proposed new Appendix 2); (2) to capitalize defined terms throughout the ROP where such terms are intended to be used in their defined meanings; and (3) to lower-case other terms that are currently capitalized in the ROP but are not defined terms." (p. 1)
  - FERC Order Approving Amendments to the ROP (01/31/2012): "Pursuant to section 215(f) of the FPA and section 39.10(a) of the Commission's regulations, we approve the proposed revisions to the NERC Rules of Procedure. We agree with NERC that the revisions do not substantively change any original definitions in the Rules of Procedure; moreover, the Rules of Procedure remains procedurally and substantively the same. In addition, the creation of Appendix 2 offers a central, readily-accessible document containing all defined terms as used within the Rules of Procedure." (P 10)

II. USAGE OF DEFINED TERM: BULK POWER SYSTEM

List of usage of the term Bulk-Power System within Reliability Standards:

	Reliability Standard	Location
1	FAC-003-3	Background and Enforcement sections
2	IRO-004-2	Compliance Monitoring
3	MOD-001-2	Purpose
4	CIP-002-5.1	Guidelines and Technical Basis
5	CIP-003-3a	Appendix 1, Response to Question 1
6	MOD-001-2	Application Guidelines, Rationale for R5
7	PER-005-2	Application Guidelines, Rationale for TO
8	TPL-007-1	Application Guidelines, Requirement R2, R7

List of ROP provisions (other than Appendix 2) where Bulk Power System occurs: The term is used throughout the ROP, including all appendices.

List defined terms that include Bulk Power System in definition narrative:

	Glossary
1	N/A (not a glossary term)
2	N/A
3	No
4	N/A
5	N/A

	ROP
1	Cyber Security Incident
2	Electric Reliability Organization or ERO
3	Interconnection
4	NERC Compliance Registry, Compliance Registry or NCR
5	Receiving Entity

6	N/A
7	N/A

9	Reliable Operation
10	N/A
11	N/A
12	N/A

6	Regional Criteria
7	Registered Entity
8	Reliability Standard
9	Reliable Operation
10	Remedial Action Directive
11	Sector
12	Submitting Entity

List of other defined terms that are included in the Bulk Power System definition narrative:

Glossary: facilities, transmission, system

ROP: Facilities, transmission, system

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: Both the ROP and Glossary definitions have been approved by FERC as tracking the definition provided in the Federal Power Act. (*See*, Glossary: FERC Order; and ROP: FERC Order on Compliance Filing, FERC Order Approving Amendments to the ROP). However, there are a number of differences in the definition narrative, including: (1) the ROP definition does not contain a hyphen for Bulk Power System, but the Glossary term does; (2) the ROP capitalizes the term "Facilities" in part (A) but the Glossary does not; (3) the ROP contains the language "electric energy supply and transmission network" whereas the Glossary provides "electric energy transmission network;" and, (4) the ROP contains the word "generating" whereas the Glossary contains "generation."

How/why the terms may be applied differently as a result of the differences: The differences are relatively minor and do not result in inconsistent or different application of the term in the Glossary or ROP. However, the different language (*i.e.*, "electric energy supply and transmission network" vs. "electric energy transmission network") may lead to confusion or imply that the terms are intended to have different meanings. Because both terms are intended to have the meaning of the definition in the Federal Power Act, the standard drafting team believes these differences should be eliminated.

Proposed revision(s): The SDT proposes revisions to both the Glossary and ROP definition in order to align the two terms and maintain consistency with the Federal Power Act. Redlines of both definitions are provided below.

Redline of Glossary definition:

Bulk- Power System:

(A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and
(B) electric energy from generation facilities needed to maintain transmission system reliability.
The term does not include facilities used in the local distribution of electric energy. (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.) Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning.

Redline of ROP, Appendix 2 definition:

Bulk Power System" means, depending on the context:

(i) (A) ~~Facilities~~ facilities and control systems necessary for operating an interconnected electric energy ~~supply and~~ transmission network (or any portion thereof)~~;~~ and

(B) electric energy from generati~~o~~n~~g~~ facilities needed to maintain transmission system reliability.

The term does not include facilities used in the local distribution of electric energy. [++] (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.) Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning.

(ii) Solely for purposes of Appendix 4E, Bulk Electric System.

Justification for decision: Both the ROP and Glossary definitions have been approved by FERC (*See*, Glossary: FERC Order; and ROP: FERC Order on Compliance Filing, FERC Order Approving Amendments to the ROP). However, there are a number of differences, mostly minor, in the two definitions. The different language may be perceived to mean that the terms are intended to have different meanings, when this is not the case. There is no reason for the terms to have differing definitions, as both terms are intended to have the meaning of the definition in Section 215 of the Federal Power Act. The SDT revisions align the terms by eliminating the unnecessary differences. Below is a summary of the proposed revisions:

(1) The SDT is proposing to remove the hyphen from the term Bulk-Power System in the Glossary because it is not being used as a compound modifier (two words coupled together to make an adjective). Because "bulk" is being used to describe the "power grid," no hyphen is needed. If instead, "bulk power" was being used to describe "grid," then a hyphen (compound modifier) would be appropriate to connect bulk-power.

(2) In both definitions, added a clarification sentence to explain that the defined terms contained in the definition (*e.g.*, system, transmission) are not capitalized in order to match the Federal Power Act definition (which does not capitalize the terms).

(3) In part (A) of the ROP definition, changed "Facilities" to lowercase "facilities" for the reason outlined in (2).

(4) In the ROP, revised "generating" to "generation" in order to match the Federal Power Act and Glossary definitions.

(5) In the ROP, revised "electric energy supply and transmission network" to "electric energy transmission network" in order to match the Federal Power Act and Glossary definitions.

Term 17: Generator Operator

Glossary Definition (differences in definition narrative indicated in red)	ROP Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
The entity that operates generating unit(s) and performs the functions of supplying energy and Interconnected Operations Services.	the entity that operates generating Facility(ies) and performs the functions of supplying energy and Interconnected Operations Services.**	The SDT is proposing to revise the Glossary definition to align with the ROP. Redline of Glossary definition: The entity that operates generating Facility(ies) ~~unit(s)~~ and performs the functions of supplying energy and Interconnected Operations Services. Additionally, the SDT notes that during the course of its work on this project, the team reviewed and assessed the quality of the definition of "Facility." The SDT believes the clarity and content of the current definition could be improved. As a result, the SDT will draft a SAR proposing to revise the definition in order to address the issues identified by the SDT.

I. HISTORY AND BACKGROUND INFORMATION REGARDING "GENERATOR OPERATOR" DEFINITION

History of Glossary term:

- Original and current version – **Effective as of 03/16/07**
  - FERC Order No. 693 (03/16/07): "In conclusion, the Commission approves the glossary. Further, pursuant to section 215(d)(5) of the FPA and § 39.5(f) of our regulations, the Commission directs ERO to modify the glossary through the Reliability Standards development process to…(2) modify the definition of "transmission operator" and "generator operator" to include aspects unique to ISO, RTO and pooled resource organizations… (P 1899)

History of ROP term:

- Original version: Effective 01/31/2012 – 03/18/15
  - NERC Petition to Revise ROP (11/29/11): "The purposes of the proposed revisions are (1) to place all definitions of defined terms used anywhere in the ROP in a single, readily-accessible location (proposed new Appendix 2); (2) to capitalize defined terms throughout the ROP where such terms are intended to be used in their defined meanings; and (3) to lower-case other terms that are currently capitalized in the ROP but are not defined terms." (p. 1)
  - FERC Order approving amendments to the ROP (01/31/2012): "Pursuant to section 215(f) of the FPA and section 39.10(a) of the Commission's regulations, we approve the proposed revisions to the NERC Rules of Procedure. We agree with NERC that the revisions do not substantively change any original definitions in the Rules of Procedure; moreover, the Rules of Procedure remains procedurally and substantively the same. In addition, the creation of Appendix 2 offers a central, readily-accessible document containing all defined terms as used within the Rules of Procedure." (P 10)

- Current version: **Effective as of 03/19/15**
  - Revisions were made by the Risk Based Registration Initiative – Replaced "units" with "Facility(ies)"
  - NERC Petition (12/11/14)
  - FERC Order (03/19/15) – Approving revised definition

II. USAGE OF DEFINED TERM: GENERATOR OPERATOR

List of usage of the term Generator Owner within Reliability Standards:

	Reliability Standard	Location
1	All Reliability Standards applicable to GOPs	Applicability
2	CIP-002-5.1	Attachment 1
3	IRO-010-1a	Appendix 1
4	PER-005-2	Application Guidelines
5	PRC-023-3	Attachment B
6	TOP-001-1a	Appendix 1
7	VAR-001-4	Application Guidelines
8	VAR-002-3	Application Guidelines
9	VAR-002-4	Application Guidelines

List of ROP provisions (other than Appendix 2) where Generator Operator occurs:

	ROP provision	Page # [Link to ROP]
1	Section 302.1	8 of 483
2	Appendix 5A: Organization Registration and Certification Manual	401 of 483
3	Appendix 5B: Statement of Compliance Registry Criteria (Revision 5.2)	433-438 of 483
4	Appendix 8: NERC Blackout and Disturbance Response Procedures, Attachment E	482 of 483

List defined terms that include Generator Operator in definition narrative:

	Glossary
1	Bulk Electric System
2	Control Center
3	Nuclear Plant Generator Operator
4	Nuclear Plant Interface Requirements
5	System Operator

	ROP
1	Bulk Electric System
2	N/A
3	N/A
4	N/A
5	N/A

List of other defined terms that are included in the Generator Operator definition narrative:

Glossary: Interconnected Operations Services

ROP: Facility(ies), Interconnected Operations Services

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The definitions were previously aligned. However, as part of the Risk Based Registration (RBR) Initiative undertaken in 2014, the ROP definition was revised and the word "unit" was replaced with "Facility(ies)." The RBR team believed it necessary to replace "unit" with "Facility(ies)" in order to incorporate the BES Definition. The RBR project work focused on changes to the ROP, and the team did not consider whether changes were needed to align any affected Glossary definitions.

How/why the terms may be applied differently as a result of the differences: The term "unit" is not a defined term in the Glossary or ROP. However, "unit" or "generating unit" are both used in definition narratives of a number of Glossary (and ROP) terms, including, but not limited to: Blackstart Resource, Bulk Electric System, Cranking Path, Economic Dispatch, Forced Outage, Host Balancing Authority, and Joint Control. The Merriam-Webster definition for unit is, "a single thing, person, or group that is a constituent of a whole." Click here for the Merriam-Webster website.

The term "Facility," on the other hand, is a defined term in the Glossary and ROP. Facility is defined as, "a set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)." Also, the term "Element" (which is used in the definition of Facility) is, "any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components."

Proposed revision(s): The SDT proposes to revise the Glossary definition to align with the ROP. No changes are proposed to the ROP.

> **Redline of Glossary definition:**
> The entity that operates generating Facility(ies) ~~unit(s)~~ and performs the functions of supplying energy and Interconnected Operations Services.

Justification for decision: The SDT is proposing to revise the Glossary definition to align with the ROP. This is because the term "unit" (used in the current Glossary definition) is not a NERC defined term, and thus introduces the possibility of inconsistent use or application of the definition. The ROP definition provides greater clarity because it uses the term "Facility(ies)," which is defined by NERC as, "a set of electrical equipment that operates as a single Bulk Electric System Element (*e.g.*, a line, a generator, a shunt compensator, transformer, etc.)." (*See also*, NERC Limited Answer to RBR Comments, pp. 6-7: "Finally, NERC's proposed changes to the definitions of "Generator Owner" and "Generator Operator" which include replacing the undefined term "generating units" with the term "Facilities," are appropriate. The term "Facilities" is defined in the NERC Glossary as a Bulk Electric System element, which ties in directly to the new BES definition. Use of the term "Facilities" has allowed NERC to eliminate the Part III threshold criteria and use the new Bulk Electric System core definition, inclusions and exclusions to identify Bulk Electric System generator assets.")

Term 18: Generator Owner

Glossary Definition (differences in definition narrative indicated in red)	ROP Appendix 2 Definitions (differences in definition narrative indicated in red)	SDT proposed revisions
Entity that owns and maintains generating units.	an entity that owns and maintains generating Facility(ies).**	The SDT is proposing to revise the Glossary definition to align with the ROP. Redline of Glossary definition: Entity that owns and maintains generating Facility(ies)~~units~~. Additionally, the SDT notes that during the course of its work on this project, the team reviewed and assessed the quality of the definition of "Facility." The SDT believes the clarity and content of the current definition could be improved. As a result, the SDT will draft a SAR proposing to revise the definition in order to address the issues identified by the SDT.

I. HISTORY AND BACKGROUND INFORMATION REGARDING "GENERATOR OWNER" DEFINITION

History of Glossary term:

- Original and current version – **Effective as of 03/16/07**
  - FERC Order No. 693 (03/16/07): "The Commission approves the glossary. The terms defined in the glossary have an important role in establishing consistent understanding of the Reliability Standards Requirements and implementation. The approval of the glossary will provide continuity in application of the glossary definitions industry-wide, and will eliminate multiple interpretations of the same term or function, which may otherwise create miscommunication and jeopardize Bulk-Power System reliability…" (P 1893)

History of ROP term:

- Original version: Effective 01/31/2012 – 03/18/15
  - NERC Petition to Revise ROP (11/29/11): "The purposes of the proposed revisions are (1) to place all definitions of defined terms used anywhere in the ROP in a single, readily-accessible location (proposed new Appendix 2); (2) to capitalize defined terms throughout the ROP where such terms are intended to be used in their defined meanings; and (3) to lower-case other terms that are currently capitalized in the ROP but are not defined terms." (p. 1)
  - FERC Order Approving Amendments to the ROP (01/31/2012): "Pursuant to section 215(f) of the FPA and section 39.10(a) of the Commission's regulations, we approve the proposed revisions to the NERC Rules of Procedure. We agree with NERC that the revisions do not substantively change any original definitions in the Rules of Procedure; moreover, the Rules of Procedure remains procedurally and substantively the same. In addition, the creation of Appendix 2 offers a central, readily-accessible document containing all defined terms as used within the Rules of Procedure." (P 10)

- Current version: **Effective as of 03/19/15**
  - Revisions were made by the Risk Based Registration Initiative – Replaced "units" with "Facility(ies)"
  - NERC Petition (12/11/14)
  - FERC Order (03/19/15) – Approving revised definition

II. USAGE OF DEFINED TERM: GENERATOR OWNER

List of usage of the term Generator Owner within Reliability Standards:

	Reliability Standard	Location
1	All Reliability Standards applicable to GOs	
2	PRC-005-1.1b	Appendix 1 Appendix 2
3	PRC-025-1	Attachment 1 Application Guideline
4	PRC-026-1	Application Guideline
5	TOP-005-2a	Appendix 2
6	TPL-007-1	Application Guideline
7	CIP-002-5.1	BES Cyber System Categorization
8	FAC-001-2	Application Guideline
9	FAC-003-3	Guideline & Technical Basis
10	IRO-010-1a	Appendix 1
11	MOD -025-2	Attachment 1
12	MOD-026-1	Attachment 1
13	MOD-027-1	Attachment 1
14	MOD-032-1	Application Guideline
15	PRC-004-3	Application Guideline
16	PRC-004-4	Application Guideline

List of ROP provisions (other than Appendix 2) where Generator Owner occurs:

	ROP provision	Page # [Link to ROP]
1	Section 302.1	8 of 483
2	Section 1702.1	105 of 483
3	Appendix 5A: Organization Registration and Certification Manual	401 of 483
4	Appendix 5B: Statement of Compliance Registry Criteria (Revision 5.2)	433 of 483 434 of 483
5	Appendix 8: NERC Blackout and Disturbance Response Procedures, Attachment E	482 of 483

List defined terms that include Generator Owner in definition narrative:

	Glossary
1	Bulk Electric System
2	Nuclear Plant Generator Operator
3	Right-of-Way
4	Transmission Customer
5	Vegetation Inspection

	ROP
1	Bulk Electric System
2	N/A
3	N/A
4	Transmission Customer
5	N/A

List of other defined terms that are included in the Generator Owner definition narrative:

Glossary: None
ROP: Facility(ies)

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The definitions were previously aligned. However, as part of the Risk Based Registration (RBR) Initiative undertaken in 2014, the ROP definition was revised and the word "unit" was replaced with "Facility(ies)." The RBR team believed it necessary to replace "unit" with "Facility(ies)" in order to incorporate the BES Definition. The RBR project work focused on changes to the ROP, and the team did not consider whether changes were needed to align any affected Glossary definitions.

How/why the terms may be applied differently as a result of the differences: The term "unit" is not a defined term in the Glossary or ROP. However, "unit" or "generating unit" are both used in definition narratives of a number of Glossary (and ROP) terms, including, but not limited to: Blackstart Resource, Bulk Electric System, Cranking Path, Economic Dispatch, Forced Outage, Host Balancing Authority, and Joint Control. The Merriam-Webster definition for unit is, "a single thing, person, or group that is a constituent of a whole." Click here for the Merriam-Webster website.

The term "Facility," on the other hand, is a defined term in the Glossary and ROP. Facility is defined as, "a set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)." Also, the term "Element" (which is used in the definition of Facility) is, "any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components."

Proposed revision(s): The SDT proposes to revise the Glossary definition to align with the ROP. No changes are proposed to the ROP.

Redline of Glossary definition:
Entity that owns and maintains generating Facility(ies)~~units~~.

Justification for decision: The SDT is proposing to revise the Glossary definition to align with the ROP. This is because the term "unit" (used in the current Glossary definition) is not a NERC defined term, and thus introduces the possibility of inconsistent use or application of the definition. The ROP definition provides greater clarity because it uses the term "Facility(ies)," which is defined by NERC as, "a set of electrical equipment that operates as a single Bulk Electric System Element (*e.g.*, a line, a generator, a shunt compensator, transformer, etc.)." (*See also*, NERC Limited Answer to RBR Comments, pp. 6-7: "Finally, NERC's proposed changes to the definitions of "Generator Owner" and "Generator Operator" which include replacing the undefined term "generating units" with the term "Facilities," are appropriate. The term "Facilities" is defined in the NERC Glossary as a Bulk Electric System element, which ties in directly to the new BES definition. Use of the term "Facilities" has allowed NERC to eliminate the Part III threshold criteria and use the new Bulk Electric System core definition, inclusions and exclusions to identify Bulk Electric System generator assets.")

Term 29: Net Energy for Load or NEL

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
Net Balancing Authority Area generation, plus energy received from other Balancing Authority Areas, less energy delivered to Balancing Authority Areas through interchange. It includes Balancing Authority Area losses but excludes energy required for storage at energy storage facilities.	net generation of an electric system plus energy received from others less energy delivered to others through interchange. It includes system losses but excludes energy required for the storage of energy at energy storage facilities.	No changes to either ROP or Glossary. The SDT recommends the terms remain unaligned. The differences in the definition narratives are appropriate given the differing uses of the term within the Glossary and ROP.

I. HISTORY AND BACKGROUND INFORMATION REGARDING "NET ENERGY FOR LOAD" DEFINITION

History of Glossary term:

- Original and current version: **Effective as of 03/16/07**
  - FERC Order No. 693 (03/16/07): "The Commission approves the glossary. The terms defined in the glossary have an important role in establishing consistent understanding of the Reliability Standards Requirements and implementation. The approval of the glossary will provide continuity in application of the glossary definitions industry-wide, and will eliminate multiple interpretations of the same term or function, which may otherwise create miscommunication and jeopardize Bulk-Power System reliability…" (P 1893)

History of ROP term:

- Original version
  - FERC Order No. 672 (02/03/06): Net Energy for Load means balancing authority area generation (less station use), plus energy received from other balancing authority areas, less energy delivered to balancing authority areas through interchange. It includes balancing authority area losses, but excludes energy required for storage at electric energy storage facilities, such as pumped storage. (P 35, FN 7)
  - FERC Order (07/20/06) - NERC's application proposes to base allocation of all costs for statutory activities on net energy for load. (P 155, 167)
  - NERC Non-Governance Compliance Filing (10/18/06): "Net Energy for Load" or "NEL" means net generation of an electric system plus energy received from others less energy delivered to others through interchange. It includes system losses but excludes energy required for the storage of energy at energy storage facilities. (Proposed Rules of Procedure, Section 202, Specific Definitions)
  - FERC Order Accepting Non-Governance Compliance Filing (01/18/07): "NERC has appropriately revised definitions in its Bylaws and its Rules of Procedure to reflect these same definitions in Order No. 672." (P 223)

- Current version: **Effective as of 01/31/2012**
  - NERC Petition to Revise ROP (11/29/11): "The purposes of the proposed revisions are (1) to place all definitions of defined terms used anywhere in the ROP in a single, readily-accessible location (proposed new Appendix 2)…" (p.1; p. 12: Definition taken from NERC Bylaws, Article 1 and ROP, Section 200).

- FERC Order Approving Amendments to the ROP (01/31/2012): "Pursuant to section 215(f) of the FPA and section 39.10(a) of the Commission's regulations, we approve the proposed revisions to the NERC Rules of Procedure. We agree with NERC that the revisions do not substantively change any original definitions in the Rules of Procedure; moreover, the Rules of Procedure remains procedurally and substantively the same. In addition, the creation of Appendix 2 offers a central, readily-accessible document containing all defined terms as used within the Rules of Procedure." (P 10)

II. USAGE OF DEFINED TERM: NET ENERGY FOR LOAD

List of usage of the term Net Energy for Load within Reliability Standards:

	Reliability Standard
1	MOD-016-1.1
2	MOD-017-0.1
3	MOD-018-0
4	MOD-021-1
5	MOD-031-1
6	TPL-006-0.1

List of ROP provisions (other than Appendix 2) where Net Energy for Load occurs:

	ROP provision	Page # [Link to ROP]
1	Section 804	71 of 483
2	Section 1101.1	84 of 483
3	Section 1101.4	84 of 483
4	Section 1103	93 of 483
5	Appendix 3A: Standards Process Manual – Footnote 10	141 of 483
6	Appendix 3B: Procedures for Election of Members of Standards Committee	186 of 483

List defined terms that include Net Energy for Load in definition narrative:

	Glossary
1	Peak Demand

	ROP
1	N/A

List of other defined terms that are included in the Net Energy for Load definition narrative:

Glossary: Balancing Authority Area

ROP: None

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The Glossary definition is more specific in that it provides "Balancing Authority Area generation" and "received from other Balancing Authority Areas" whereas the ROP definition refers more broadly to "generation of an electric system" and "received from others."

How/why the terms may be applied differently as a result of the differences: The differences are significant and should remain due to the manner in which these terms are applied in their respective documents (ROP or Glossary). For example, as outlined above, FERC approved the ERO's proposal to base allocation of all costs for

statutory activities on net energy for load (See ROP, Section 1100). In the context of Reliability Standards, the collection of Net Energy for Load data is required for certain modeling standards (See MOD-031-3).

Proposed revision(s): Alignment is not recommended by SDT because the differences in the definition narrative are appropriate given the different uses of the term within the Glossary and ROP.

Justification for decision: The differences are significant and should remain due to the manner in which these terms are applied in their respective documents (ROP or Glossary).

Term 40: Reliability Standard

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
A requirement, approved by the United States Federal Energy Regulatory Commission under this Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk-Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity.	a requirement to provide for Reliable Operation of the Bulk Power System, including without limiting the foregoing, requirements for the operation of existing Bulk Power System Facilities, including cyber security protection, and including the design of planned additions or modifications to such Facilities to the extent necessary for Reliable Operation of the Bulk Power System, but the term does not include any requirement to enlarge Bulk Power System Facilities or to construct new transmission capacity or generation capacity. A Reliability Standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.	The SDT is proposing revisions to both the Glossary and ROP definitions, as follows: Redline of Glossary definition: A requirement, approved by the United States Federal Energy Regulatory Commission under ~~this~~ Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk~~-~~ Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk~~-~~ Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk~~-~~ Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.) Redline of ROP definition: a requirement, approved by the United States Federal Energy Regulatory Commission under Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System]~~,~~ ~~including without limiting the foregoing,~~ The term includes requirements for the operation of existing bulk-power system [Bulk Power System] ~~Facilities~~facilities, including cyber~~-~~security protection, and ~~including~~ the design of planned additions or modifications to such ~~Facilities~~ facilities to the extent necessary for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System], but the term does not include any requirement to enlarge ~~Bulk Power System~~ such ~~Facilities~~ facilities or to construct new transmission capacity or generation capacity.++ (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.) In certain contexts, this term may also refer to a "Reliability Standard" that is in the process of being developed, or not yet approved or recognized by FERC or an applicable governmental authority in other jurisdictions. ~~A Reliability Standard~~

		~~shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.~~

I. HISTORY AND BACKGROUND INFORMATION REGARDING "RELIABILITY STANDARD" DEFINITION

History of Glossary term:

- Original version: 03/16/07 - 07/08/13
  - FERC Order No. 693 (03/16/07) - "The Commission directs the ERO to modify the glossary through the Reliability Standards development process to include the statutory definitions of the terms Bulk-Power System, Reliable Operation and Reliability Standard. However, this determination does not negate our discussion in the Applicability section of the Final Rule. While the glossary should be revised to include the statutory definition of Bulk-Power System, the Reliability Standards refer to the bulk electric system, which is also defined in the glossary." (P 1894)

- Current version: **Effective as of 07/09/13**
  - Revised by Project 2012-08.1 Phase 1 of the Glossary Updates for Statutory Definitions
  - NERC Petition (05/10/13) - The proposed definition borrows heavily from FPA, but makes slight alterations.

"The term "Reliability Standard" is defined in section 215 of the FPA as follows:

> (3) The term 'reliability standard' means a requirement, approved by the Commission under this section, to provide for reliable operation of the bulk-power system. The term includes requirements for the operation of existing bulk-power system facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation of the bulk-power system, but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity.

The proposed definition of the term "Reliability Standard" for inclusion in the NERC Glossary is as follows:

> "Reliability Standard" means a requirement, approved by the United States Federal Energy Regulatory Commission under Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for Reliable Operation of the Bulk-Power System. The term includes requirements for the operation of existing Bulk-Power System facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for Reliable Operation of the Bulk-Power System, but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity.

As noted herein, the proposed definition of "Reliability Standard" is substantively identical to the definition in section 215 of the FPA, although the terms "Bulk-Power System" and "Reliable Operation" are capitalized to reflect the fact that they are defined terms and slight modifications were necessary to clarify the terms "Commission" and "section" (contained in the section 215 definition of the term "Reliability Standard").

"Commission" refers to the Federal Energy Regulatory Commission in the United States and applicable governmental authorities approving, or recognizing the standard, in other jurisdictions; similarly, "section" has been replaced with "section 215 of the Federal Power Act."

These minor modifications are fully consistent with section 215 and the recognized need for international agreements with the governments of Canada and Mexico to provide for effective compliance with Reliability Standards and the effectiveness of the ERO in the United States and Canada or Mexico. For these reasons, the proposed definition of "Reliability Standard" should be accepted in compliance with the Commission's directive in Order No. 693." (pp. 7-8)

- FERC Order (07/9/13) - Letter order approving proposed definitions

History of ROP term:

- Original version:
  - NERC Non-Governance Compliance Filing (10/18/06): "NERC has also revised definitions in its Rules of Procedure to match definitions in Section 215(a) of the Federal Power Act and/or Part 39 of the Commission's regulations, including 'bulk power system', 'electric reliability organization,' 'reliable operation,' and 'reliability standard'." (pp. 71-72)
    - " 'Reliability standard' means a requirement to provide for reliable operation of the bulk power system, including without limiting the foregoing, requirements for the operation of existing bulk power system facilities, including cyber security protection, and including the design of planned additions or modifications to such facilities to the extent necessary for reliable operation of the bulk power system, but the term does not include any requirement to enlarge bulk power system facilities or to construct new transmission capacity or generation capacity. A reliability standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the applicable governmental authority.' (Citing, Attachment 1, Revised ROP, at Section 202)
  - FERC Order Accepting Non-Governance Compliance Filing (01/18/07): "NERC has appropriately revised definitions in its Bylaws and its Rules of Procedure to reflect these same definitions in Order No. 672." (P 223)

- Current version: **Effective as of 01/31/2012**
  - NERC Petition to Revise ROP (11/29/11): "The purposes of the proposed revisions are (1) to place all definitions of defined terms used anywhere in the ROP in a single, readily-accessible location (proposed new Appendix 2); (2) to capitalize defined terms throughout the ROP where such terms are intended to be used in their defined meanings; and (3) to lower-case other terms that are currently capitalized in the ROP but are not defined terms." (p. 1)
  - FERC Order Approving Amendments to the ROP (01/31/2012): "Pursuant to section 215(f) of the FPA and section 39.10(a) of the Commission's regulations, we approve the proposed revisions to the NERC Rules of Procedure. We agree with NERC that the revisions do not substantively change any original definitions in the Rules of Procedure; moreover, the Rules of Procedure remains procedurally and substantively the same. In addition, the creation of Appendix 2 offers a central, readily-accessible document containing all defined terms as used within the Rules of Procedure." (P 10)

II. USAGE OF DEFINED TERM: RELIABILITY STANDARD

List of usage of the term "Reliability Standard" within the Complete Set of Reliability Standards: The term appears at least 330 times within the Complete Set of NERC Reliability Standards. The overwhelming majority of these uses are in reference to a particular Reliability Standard (*e.g.*, Reliability Standard FAC-003-3). Such uses do not touch upon the concept of "Reliability Standard" in a way that revising the definition of the term would have any material impact. It also appears passim in the "Applicability" Section of the new CIP v5 Standards. Again, revision would have no material impact. Also, it appears in the "Effective Date" of many Reliability Standards. Again, revision would have no material impact.

List of ROP provisions (other than Appendix 2) where Reliability Standard occurs: The term appears over 850 times in the ROP. A number of the ROP provisions refer or apply to Reliability Standards that are currently under development, or are approved by the NERC Board of Trustees, but not yet approved by FERC or another applicable governmental authority.

List defined terms that include Reliability Standard in definition narrative:

	Glossary
1	Burden (not defined term)
2	Compliance Monitor (not defined term)
3	Control Performance Standard (not defined term)
4	Disturbance Control Standard (not defined term)
5	Remedial Action Scheme
6	Extraordinary Contingency (referencing WECC Reliability Standard)
7	Functionally Equivalent Protection System
8	Functionally Equivalent RAS

ROP [Link to ROP]
The term is used in 38 ROP, Appendix 2 definitions.

List of all other defined terms that are included in the Reliability Standard definition narrative:

Glossary: Reliable Operation, Bulk-Power System, facility(ies)
ROP: Reliable Operation, Bulk Power System, Facility, Applicable Governmental Authority

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The Glossary definition is somewhat more limiting because it defines "Reliability Standard" as a "requirement approved by the United States Federal Energy Regulatory Commission…" The ROP definition is broader than the Glossary definition because it does not include the "approved" language and includes those standards that are not yet FERC-approved.

How/why the terms may be applied differently as a result of the differences: The difference in these definitions is meaningful. The Glossary term is narrower than the ROP term. This difference may cause confusion when applying the definition in the ROP when addressing standards that are currently under development, or approved by the NERC Board of Directors, but not yet FERC-approved.

Proposed revision(s): The drafting team proposes revisions to both the Glossary and ROP definitions.

Redline of Glossary definition:

A requirement, approved by the United States Federal Energy Regulatory Commission under ~~this~~ Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk~~-~~ Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk~~-~~ Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk~~-~~ Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)

Redline of ROP Appendix 2 definition:

a requirement, approved by the United States Federal Energy Regulatory Commission under Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System]~~., including without limiting the foregoing,~~ The term includes requirements for the operation of existing bulk-power system [Bulk Power System] ~~Facilities~~facilities, including cyber~~-~~security protection, and ~~including~~ the design of planned additions or modifications to such ~~Facilities~~ facilities to the extent necessary for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System], but the term does not include any requirement to enlarge ~~Bulk Power System~~ such ~~Facilities~~ facilities or to construct new transmission capacity or generation capacity.~~+~~+ (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.) In certain contexts, this term may also refer to a "Reliability Standard" that is in the process of being developed, or not yet approved or recognized by FERC or an applicable governmental authority in other jurisdictions. ~~A Reliability Standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.~~

Justification for decision: The SDT believes the proposed revisions will allow the ROP definition to align with the Glossary definition, which tracks the language in the Federal Power Act. The Glossary was revised through Project 2012-08.1 to address a FERC directive to adopt the Federal Power Act definition. The Project 2012-08.1 drafting team noted in their response to industry comments that any necessary revisions to the ROP definition would be made through a separate project. The Project 2015-04 SDT is now proposing to make these revisions to align the definitions. Because a number of ROP provisions refer or apply to Reliability Standards that are currently under development, or are approved by the NERC Board of Trustees, but not yet FERC-approved, the SDT is proposing to add qualifying language to the ROP definition. The ROP definition explains that in certain contexts, "Reliability Standard" may refer to a standard that is in the process of being developed, and not yet FERC-approved.

Term 44: Sink Balancing Authority

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
The Balancing Authority in which the load (sink) is located for an Interchange Transaction and any resulting Interchange Schedule.	the Balancing Authority in which the Load (sink) is located for an Interchange Transaction.**	The SDT is proposing to revise the ROP definition to align with the Glossary definition. Redline of ROP definition: the Balancing Authority in which the ~~Load~~ load (sink) is located for an Interchange Transaction and any resulting Interchange Schedule.**

I. HISTORY AND BACKGROUND INFORMATION REGARDING "SINK BALANCING AUTHORITY" DEFINITION

History of Glossary term:

- Original version: FERC approved 3/16/2007: "The Balancing Authority in which the load (sink) is located for an Interchange Transaction. (This will also be a Sending Balancing Authority for the resulting Interchange Schedule.)"

- Current version: **Effective as of 10/01/2014**
  - Revisions made by Project 2008-12 Coordinate Interchange Standards
  - NERC Petition (02/27/2014) - "The proposed revisions to "Sink Balancing Authority" are intended to clarify the various Balancing Authorities involved in the implementation of Interchange and their relationships with regards to Interchange." (p. 33)
  - FERC Order (06/30/2014) – Letter order approving the revised Glossary definition

History of ROP term:

- Current version: **Effective as of 07/01/13**
  - NERC Petition (11/29/2011) - Added Appendix 2 to ROP and adopted existing Glossary definition for Sink Balancing Authority (p. 14)
  - FERC Order (01/31/2012) - "These revisions are being proposed as a result of P 93 of the Commission's Order issued October 21, 2010, in Docket No. RR10-11-000, in which the Commission invited NERC to submit a filing making consistent use of defined terms throughout the ROP and Appendices." (p. 1)
  - NERC Petition (01/25/12) – Minor revisions to "Sink Balancing Authority" to reflect changes resulting from new BES Definition

II. USAGE OF DEFINED TERM: SINK BALANCING AUTHORITY

List of usage of the term Sink Balancing Authority within Reliability Standards:

	Reliability Standard
1	BAL-006-2
2	INT-001-3
3	INT-004-3.1
4	INT-005-3

5	INT-006-4
6	INT-010-2.1
7	IRO-006-East-1
8	MOD-028-2

List of ROP provisions (other than Appendix 2) where Sink Balancing Authority occurs: None.

List defined terms that include Sink Balancing Authority in definition narrative:

	Glossary
1	Intermediate Balancing Authority
2	Request for Interchange (Archive)
3	Contributing Schedule
4	Relief Requirement (Archive)

	ROP
1	N/A
2	N/A
3	N/A
4	N/A

List of other defined terms that are included in the Sink Balancing Authority definition narrative:

Glossary: Balancing Authority, load, Interchange Transaction, Interchange Schedule
ROP: Balancing Authority, Load, Interchange Transaction

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: There are two differences between the Glossary and ROP definitions: (1) the Glossary definition does not capitalize the term "load" whereas the ROP definition does; and, (2) the Glossary definition includes "an Interchange Transaction and any resulting Interchange Schedule" whereas the ROP definition only provides "an Interchange Transaction."

How/why the terms may be applied differently as a result of the differences: The language added through the Project 2008-12 Coordinate Interchange Standards did not impact or change the meaning of the definitions. The changes to the Glossary definition clarified the various Balancing Authorities involved in the implementation of Interchange and their relationship to Interchange. Additionally, the Glossary definition correctly uses lowercase for "load" rather than the defined term, which is appropriate given that the use of load in the narrative does not appear to have the meaning of the NERC definition. The SDT is proposing to correct the ROP definition to reflect the lowercase usage of the word "load" so that it is aligned with the Glossary definition.

Proposed revision(s): The SDT proposes to revise the ROP definition to align with the Glossary definition.

Redline of ROP definition:

the Balancing Authority in which the ~~Load~~ load (sink) is located for an Interchange Transaction and any resulting Interchange Schedule.**

Justification for decision: The original Glossary definition became effective in March 2007. The ROP definition adopted the Glossary definition when Appendix 2 was created in 2012. Note that the ROP definition is marked with a double asterisk (**), indicating it was taken from the Glossary. Subsequently, in 2014, the Glossary term was revised to provide greater clarity. The ROP definition was not updated to reflect the revised Glossary definition.

Term 45: Source Balancing Authority

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
The Balancing Authority in which the generation (source) is located for an Interchange Transaction and for any resulting Interchange Schedule.	the Balancing Authority in which the generation (source) is located for an Interchange Transaction.**	The SDT is proposing to revise the ROP definition to align with the Glossary definition. Redline of ROP definition: the Balancing Authority in which the generation (source) is located for an Interchange Transaction and for any resulting Interchange Schedule.**

I. HISTORY AND BACKGROUND INFORMATION REGARDING "SOURCE BALANCING AUTHORITY" DEFINITION

History of Glossary term:

- Original version: Effective dates 03/16/07 – 09/30/14 (Version 0: "The Balancing Authority in which the generation (source) is located for an Interchange Transaction. This will also be a Sending Balancing Authority for the resulting Interchange Schedule.")

- Current version: **Effective as of 10/01/2014**
  - Revisions made by Project 2008-12 Coordinate Interchange Standards
  - NERC Petition (02/27/14) - "The proposed revisions to "Source Balancing Authority" are intended to clarify the various Balancing Authorities involved in the implementation of Interchange and their relationships with regards to Interchange." (p. 34)
  - FERC Order (06/30/2014) – FERC letter order approving revised Glossary definition

History of ROP term:

- Current version: **Effective as of 01/31/2012**
  - NERC Petition (11/29/2011) - Added Appendix 2 to ROP and adopted existing Glossary definition for Adjacent Balancing Authority (see p. 9)
  - FERC Order (01/31/2012) - "These revisions are being proposed as a result of P 93 of the Commission's Order issued October 21, 2010, in Docket No. RR10-11-000, in which the Commission invited NERC to submit a filing making consistent use of defined terms throughout the ROP and Appendices." (p. 1)

II. USAGE OF DEFINED TERM: SOURCE BALANCING AUTHORITY

List of all usage of the term Source Balancing Authority within Reliability Standards:

	Reliability Standard
1	BAL-006-2
2	INT-005-3
3	INT-006-4
74	MOD-028-2

List of all ROP provisions (other than Appendix 2) where Source Balancing Authority occurs: None.

List all defined terms that include Source Balancing Authority in definition narrative:

	Glossary
1	Intermediate Balancing Authority
2	Contributing Schedule

	ROP
1	N/A
2	N/A

List of all other defined terms that are included in the Source Balancing Authority definition narrative:

Glossary**:** Balancing Authority, Interchange Transaction, Interchange Schedule

ROP: Balancing Authority, Interchange Transaction

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The Glossary definition includes "and for any resulting Interchange Schedule" whereas the ROP does not.

Explain how/why the terms may be applied differently as a result of the differences: The language added through the Project 2008-12 Coordinate Interchange Standards did not impact or change the meaning of the definitions. The changes to the Glossary definition clarified the various Balancing Authorities involved in the implementation of Interchange and their relationship to Interchange.

Proposed revision(s). The SDT proposes to revise the ROP definition to align with the Glossary definition.

Redline of ROP definition:

the Balancing Authority in which the generation (source) is located for an Interchange Transaction and for any resulting Interchange Schedule.**

Justification for decision: The original Glossary definition became effective in March 2007. The ROP definition adopted the Glossary definition when Appendix 2 was created in 2012. Note that the ROP definition is marked with a double asterisk (**), indicating it was taken from the Glossary. Subsequently, in 2014, the Glossary term was revised to provide greater clarity. The ROP definition was not updated to reflect the revised Glossary definition.

Term 48: System Operating Limit (SOL)

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
The value (such as MW, MVar, Amperes, Frequency or Volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • Facility Ratings (Applicable pre- and post-Contingency equipment or facility ratings) • Transient Stability Ratings (Applicable pre- and post-Contingency Stability Limits) • Voltage Stability Ratings (Applicable pre- and post-Contingency Voltage Stability) • System Voltage Limits (Applicable pre- and post-Contingency Voltage Limits)	the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria.**	The SDT is proposing to revise both the Glossary and ROP, as follows: Redline of Glossary definition: The value (such as MW, MVar, ~~A~~amperes, ~~Frequency~~ frequency or ~~Volts~~volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • Facility Ratings (~~Applicable~~ applicable pre- and post-Contingency ~~equipment~~ Equipment Ratings or ~~facility~~ Facility ~~ratings~~Ratings) • ~~Transient~~ transient ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Stability~~ stability ~~Limits~~limits) • ~~Voltage~~ voltage ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Stability~~stability) • ~~System~~ system ~~Voltage~~ voltage ~~Limits~~ limits (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Limits~~limits) Redline of ROP definition: the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • facility ratings (applicable pre- and post-contingency equipment ratings or facility ratings) • transient stability ratings (applicable pre- and post-contingency stability limits) • voltage stability ratings (applicable pre- and post-contingency voltage stability) • system voltage limits (applicable pre- and post-contingency voltage limits).**

I. HISTORY AND BACKGROUND INFORMATION REGARDING "SYSTEM OPERATING LIMIT" DEFINITION

History of Glossary term:

- Original and current version: **Effective date 07/08/13**
  - FERC Order No. 693 (03/16/07) - "The Commission directs the ERO to modify the glossary through the Reliability Standards development process to include the statutory definitions of the terms Bulk-Power System, Reliable Operation and Reliability Standard. However, this determination does not negate our discussion in the Applicability section of the Final Rule. While the glossary should be revised to include the statutory definition of Bulk-Power System, the Reliability Standards refer to the bulk electric system, which is also defined in the glossary." (P 1894)

History of ROP term:

- Current version: **Effective as of 01/31/2012**
  - NERC Petition (11/29/2011) - Added Appendix 2 to ROP and adopted existing Glossary definition for System Operating Limit (see p. 14)
  - FERC Order (01/31/2012) - "These revisions are being proposed as a result of P 93 of the Commission's Order issued October 21, 2010, in Docket No. RR10-11-000, in which the Commission invited NERC to submit a filing making consistent use of defined terms throughout the ROP and Appendices."

II. USAGE OF DEFINED TERM: SYSTEM OPERATING LIMIT

List of usage of the term "System Operating Limit" within Reliability Standards: The term appears over fifty times within the Complete Set of NERC Reliability Standards. A majority of these occurrences are in the FAC, IRO and TOP standards (the term also appears in CIP, EOP, MOD, PER, and PRC standards).

List of ROP provisions (other than Appendix 2) where System Operating Limit occurs:

	ROP provision	Page # [Link to ROP]
1	Appendix 4C – CMEP, Section 1.1.11	216 of 483
2	NERC Blackout and Disturbance Response Procedures	468 of 483

List defined terms that include System Operating Limit in definition narrative:

	Glossary
1	Burden
2	Constrained Facility
3	N/A
4	Interconnection Reliability Operating Limit
5	Total Flowgate Capability

	ROP
1	N/A
2	N/A
3	Exception Report
4	Interconnection Reliability Operating Limit
5	N/A

List of other defined terms that are included in the System Operating Limit definition narrative:

Glossary: system, Facility Rating, Contingency, Equipment Rating

ROP: system

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The Glossary definition explains that System Operating Limits are based on certain operating criteria, and it provides a non-exhaustive listing of what that operating criteria may be. The ROP does not contain this additional level of detail.

How/why the terms may be applied differently as a result of the differences: The definitions are similar, however, the Glossary provides more clarity by giving examples of what the operating criteria might be. While the Glossary definition may provide more clarity with the examples, the definitions are consistent with one another and the differences should not result in different application of the term.

Proposed revision(s): The SDT is proposing revisions to both the Glossary and ROP definitions.

Redline of Glossary definition:

The value (such as MW, MVar, ~~A~~amperes, ~~Frequency~~ frequency or ~~Volts~~volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to:

- Facility Ratings (~~Applicable~~ applicable pre- and post-Contingency ~~equipment~~ Equipment Ratings or ~~facility~~ Facility ~~ratings~~Ratings)
- ~~Transient~~ transient ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Stability~~ stability ~~Limits~~limits)
- ~~Voltage~~ voltage ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Stability~~stability)
- ~~System~~ system ~~Voltage~~ voltage ~~Limits~~ limits (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Limits~~limits).

Redline of ROP definition:

the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to:

- facility ratings (applicable pre- and post-contingency equipment ratings or facility ratings)
- transient stability ratings (applicable pre- and post-contingency stability limits)
- voltage stability ratings (applicable pre- and post-contingency voltage stability)
- system voltage limits (applicable pre- and post-contingency voltage limits).**

Justification for decision: The ROP definition adopted the Glossary definition when Appendix 2 was created in 2012. Note that the ROP definition is marked with a double asterisk (**), indicating it was taken from the Glossary. However, despite the double asterisk (**) indicator, the ROP definition only adopted a portion of the Glossary definition. The SDT is proposing to align the ROP with the Glossary definition. The Glossary definition

provides more clarity with the non-exhaustive list of examples. Additionally, the SDT revised the Glossary definition to lowercase those terms that are not defined terms, and thus, should not be capitalized in the definition narrative.

Part IV: Group 2 recommendations

There are a total of six (6) Group 2 cross-over terms:

Term 8: Critical Assets

Term 9: Critical Cyber Assets

Term 10: Cyber Assets

Term 11: Cyber Security Incident

Term 25: Interconnection

Term 46: Special Protection System

The SDT is recommending revisions to one (1) of the Group 2 cross-over terms. Below is an overview of the SDT research, assessment, proposed revision(s), and justification for each of the recommendations.

CIP-RELATED CROSS-OVER TERMS

Term 8: Critical Assets

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
Glossary term (inactive 03/31/16): Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the Bulk Electric System.	Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the Bulk Electric System.**	The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. For the reasons outlined below, the SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.

Term 9: Critical Cyber Assets

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
Glossary term (inactive 03/31/2016): Cyber Assets essential to the reliable operation of Critical Assets.	Cyber Assets critical to the reliable operation of Critical Assets.**	The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. For the reasons outlined below, the SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.

Term 10: Cyber Assets

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
Current definition (inactive 3/31/16):		The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that

Programmable electronic devices and communication networks including hardware, software, and data. Revised definition (effective 4/1/2016): Programmable electronic devices, including the hardware, software, and data in those devices.	programmable electronic devices and communication networks including hardware, software, and data.** programmable electronic devices and communication networks including hardware, software, and data.**	would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. For the reasons outlined below, the SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.

Term 11: Cyber Security Incident

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
Current definition (inactive 03/31/16): Any malicious act or suspicious event that: • Compromises, or was an attempt to compromise, the Electronic Security Perimeter or Physical Security Perimeter of a Critical Cyber Asset, or, • Disrupts, or was an attempt to disrupt, the operation of a Critical Cyber Asset. Revised definition (effective 04/01/16): A malicious act or suspicious event that: • Compromises, or was an attempt to compromise, the Electronic Security Perimeter or Physical Security Perimeter or, • Disrupts, or was an attempt to disrupt, the operation of a BES Cyber System.	any malicious or suspicious event that disrupts, or was an attempt to disrupt, the operation of those programmable electronic devices and communications networks including hardware, software and data that are essential to the Reliable Operation of the Bulk Power System.++ any malicious or suspicious event that disrupts, or was an attempt to disrupt, the operation of those programmable electronic devices and communications networks including hardware, software and data that are essential to the Reliable Operation of the Bulk Power System.++	The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. For the reasons outlined below, the SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.

I. HISTORY AND BACKGROUND INFORMATION REGARDING THE CIP-RELATED CROSS OVER TERMS

In 2008, in Order No. 706, FERC approved a number of revised CIP standards and CIP-related Glossary definitions, including the cross-over terms that are currently under review in this project. Thereafter, in 2011, NERC filed a Petition requesting approval to create a ROP Appendix 2 which would house all of the defined terms used or necessary for the ROP provisions. In 2012, FERC issued an Order Approving Amendments to the ROP. In the ROP, Appendix 2, defined terms that were taken from the Glossary were marked with a double asterisk (**); whereas terms taken from the Federal Power Act were marked with a double plus sign (++). All of the cross-over terms that are currently under review by the SDT were added to the ROP, Appendix 2 in this filing. Of those terms, three terms-- Critical Assets, Critical Cyber Assets, and Cyber Assets-- are marked with a double asterisk (**) because they were

taken from the Glossary; one term-- Cyber Security Incident-- is marked with a double plus sign (++) because it was taken from the Federal Power Act.

In 2012, Project 2008-06 made substantial revisions to the CIP Reliability Standards, including revisions to a number of the defined terms used therein. In NERC's petition for approval of the revised standards, "NERC proposes nineteen CIP-related definitions for inclusion in the NERC Glossary. This includes fifteen new definitions and four revised definitions, as well as the retirement of two definitions." See, FERC Order No. 791 P 113.
The 15 newly proposed Glossary definitions included:

1. BES Cyber Asset
2. BES Cyber System
3. BES Cyber System Information
4. CIP Exceptional Circumstances
5. CIP Senior Manager
6. Control Center
7. Dial-up Connectivity
8. Electronic Access Control or Monitoring Systems (EACMS)
9. Electronic Access Point (EAP)
10. External Routable Connectivity
11. Interactive Remote Access
12. Intermediate System
13. Physical Access Control Systems (PACS)
14. Protected Cyber Assets (PCA)
15. Reportable Cyber Security Incident

Also, NERC proposed revisions to four existing Glossary definitions:

1. Cyber Assets
2. Cyber Security Incident
3. Electronic Security Perimeter (ESP)
4. Physical Security Perimeter (PSP)

Further, NERC proposed to retire two existing Glossary definitions:

1. Critical Assets
2. Critical Cyber Assets

These proposed revisions to the Glossary terms were approved by FERC, and become effective March 31, 2016 (retired terms) and April 01, 2016 (new and revised terms). (*See*, FERC Order No. 791). However, no conforming changes were proposed for the defined terms contained in the ROP, Appendix 2. As a result, beginning March 31, 2016, a number of CIP-related defined terms will not be aligned.

II. USAGE OF CIP-RELATED DEFINED TERMS

The four (4) cross-over terms at issue are used throughout the CIP Reliability Standards. Also, the terms are used in a number of ROP provisions, including:

1. Section 400 – Compliance Enforcement, Section 401.10 and 403.13 (*see* pp. 29-39 of 483);
2. Section 1500 – Confidential Information (*see*, p. 96 of 483);
3. Appendix 4C: Compliance Monitoring and Enforcement Program, Section 1.1.5 – Definitions (*see*, p. 262 of 483);
4. Appendix 4C: Compliance Monitoring and Enforcement Program – Attachment 2 - Section 1.5.10, 1.7.4 (*see*, pp. 291, 299, 301 of 483);

5. Appendix D – Technically Feasible Exception Procedure (*see*, pp. 309-310 of 483);
6. Compliance and Certification Committee Hearing Procedures - 1.1.5 Definitions (*see*, pp. 334, 336, 357, 363, 364 of 483);
7. Appendix 5B – Statement of Compliance Registry Criteria (see, p. 438 of 483);
8. Hearing Procedures for Use in Appeals of Certification Matters (*see*, pp. 373, 384, 389 of 483)

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

The SDT is not proposing any revisions to the cross-over terms at this time. This is because the changes that are necessary to align the four cross-over terms would also necessitate a large number of other changes that are outside the scope of the SAR for this project. For example, if changes were made to revise the ROP definition to align with the future enforceable Glossary definition of Cyber Security Incident, three (3) new defined terms would need to be introduced to the ROP-- BES Cyber System, Physical Security Perimeter and Electronic Security Perimeter. Also, the defined term "BES Cyber System" contains the defined term "BES Cyber Asset," which is not defined in the ROP. These four defined terms would need to be added to the ROP because they are not currently defined terms in the ROP, and the definition narratives that would be adopted contain the defined terms.

Another example is the terms, Critical Asset and Critical Cyber Asset, which were retired by the Project 2008-06 team. The CIP version 5 drafting team retired these two terms in the Glossary because the revisions associated with the Version 5 CIP standards "moves away from the CIP version 4 'bright-line' approach of only identifying Critical Assets (and applying CIP requirements only to their associated Critical Cyber Assets), to requiring a minimum classification of 'Low Impact' for all BES Cyber Systems." (See, FERC Order No. 791, P14). In conjunction with the retirement of these two Glossary terms, however, the CIP SDT made a number of revisions to other defined terms and added new definitions to reflect the paradigm shift to classifying BES Cyber Systems. Therefore, in order for this drafting team to adopt the approach taken by the CIP version 5 changes, the team could not simply retire the two cross-over terms that are currently within the scope of the SAR. Rather, the team would have to make all of the other corresponding and necessary changes that were made in conjunction with the CIP version 5 work. For example, the team added the new term, "BES Cyber Asset" to replace the retired terms. This is not a defined term in the ROP, so it would need to be added to Appendix 2. The Glossary definition of "BES Cyber Asset" includes two defined terms-- Electronic Security Perimeter and Cyber Asset. These two defined terms would need to be added to the ROP and align with the Glossary definition.

Additionally, any changes to the ROP definitions would necessitate a thorough review and analysis of the provisions of the ROP that use any of those terms-- both defined and lowercase usage. This is because the ROP currently contains a number of provisions which use the cross-over terms according to the manner in which they are currently defined in the ROP. The alignment changes may alter or affect the meaning of these ROP provisions (see above listing for examples of ROP provisions that use the current ROP definitions).

For the reasons outlined above, the SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.

Term 25: Interconnection

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
Currently effective (inactive as of 06/30/16): When capitalized, any one of the three major electric system networks in North America: Eastern, Western, and ERCOT. FERC-approved (effective date 07/01/16) When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.	a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++	The SDT is proposing to revise both the Glossary and ROP definitions (effective no earlier than 07/01/16), as follows: Redline of Glossary definition: A geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control. When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec. Redline of ROP definition: a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++ When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.**

I. HISTORY AND BACKGROUND INFORMATION REGARDING "INTERCONNECTION" DEFINITION

History of Glossary term:

- Original and current version: Effective 03/16/07 – current
  - FERC Order No. 693 (03/16/07) "When capitalized, any one of the three major electric system networks in North America: Eastern Western, and ERCOT." (P 1898)

- Future version: **Effective beginning 07/01/16**
  - Revised by Project 2010-14.1 - Phase 1 Balancing Authority Reliability-based Controls.
  - NERC Petition (04/02/14) – Revised definition to include Quebec interconnection.
  - FERC Order No. 810 (04/16/15) – Revised definition approved.

History of ROP term:

- Original version: Effective 03/17/07 – 01/30/12). Version 0: "Interconnection" means an electric energy supply and transmission network in which the component electric facilities are interconnected and operated synchronously and to which the only connections to other electric networks are asynchronous. (*See*, FERC Order Certifying NERC as ERO).

- Revised and current version: **Effective as of 01/31/2012**
  - o FERC Order (01/31/2012) – The current version is taken from 18 C.F.R. Part 39.1 and the Federal Power Act, Section 215.

II. USAGE OF DEFINED TERM: INTERCONNECTION

List of all usage of the term Interconnection within Reliability Standards: The term appears in at least thirty-five (35) times in the Complete Set of Reliability Standards. The majority of the occurrences are in the BAL, EOP, IRO, MOD and TOP standards.

List of all ROP provisions (other than Appendix 2) where Interconnection occurs:

	ROP provision	Page # [Link to ROP]
1	Section 300, 302, 312	8-20 of 483
2	Section 803	70 -71 of 483
3	Section 1102	84 of 483
4	Appendix 3A – Standards Process Manual, Section 9	167 of 483
5	Appendix 5B – Statement of Compliance Registry Criteria (Revision 5.2)	431-434 of 483
6	Appendix 5C – Exceptions to BES Definition	452 of 483
7	NERC Blackout and Disturbance Procedures	469-473 of 483

List all defined terms that include Interconnection in definition narrative:

	Glossary
1	Adverse Reliability Impact
2	Area Control Error
3	Balancing Authority
4	Bulk Electric System
5	Burden

2	N/A
3	Balancing Authority
4	Bulk Electric System
5	N/A
6	N/A
7	N/A
8	N/A
9	N/A
10	N/A
11	Interchange Distribution Calculator
12	N/A
13	N/A
14	N/A
15	N/A
16	N/A

List of all other defined terms that are included in the Interconnection definition narrative:

Glossary: None

ROP: Bulk Power System; Reliable Operation; Facilities

III. DRAFTING TEAM ANALYSIS AND ASSESSMENT

Explanation of differences in definition narratives: The ROP definition provides a description of what an interconnection is conceptually, and the criteria for use in identifying one. The Glossary definition, on the other hand, "defines" the term by applying the ROP definition and identifying the specific geographical areas that meet the criteria outlined in the ROP definition. The difference in these two definitions would be similar to defining the term "Federal Holiday" by listing all eleven federal holidays in the United States (*e.g.*, New Year's Day, MLK Jr. Day, Inauguration Day, etc.) as opposed to defining the term by describing what constitutes a "Federal Holiday" in the abstract (*i.e.*, "an authorized holiday which has been recognized by the US government and on which non-essential federal government offices are closed").

How/why the terms may be applied differently as a result of the differences: The ROP definition is broader than the Glossary because it provides a description of what constitutes an interconnection, as opposed to identifying the specific geographical areas in North America that currently constitute an interconnection. Because the Glossary limits application of the definition to the specific interconnections identified therein, it could be perceived as intended to be more limiting and/or intentionally different than the ROP definition.

Proposed revision(s). The SDT proposes revisions to both the Glossary and ROP definition in order to align the two terms and maintain consistency with the Federal Power Act. Redlines of both definitions are provided below.

Redline of Glossary definition:

A geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control. When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.

Redline of ROP definition:

a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++ When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.**

Justification for decision: The ROP definition tracks the Federal Power Act (note it is marked with ++ indicating such). In order to align the two definitions, without losing the clarity provided by the FERC-approved Glossary definition, which specifically identifies the current Interconnections in North America, the SDT is proposing to combine the two definitions. However, because the recently FERC-approved Glossary definition is not effective until July 1, 2016, the SDT is proposing that the alignment revisions do not take effect until July 1, 2016, at the earliest.

Term 46: Special Protection System

Glossary Definition (differences in definition narrative indicated in red)	ROP, Appendix 2 Definition (differences in definition narrative indicated in red)	SDT proposed revisions
An automatic protection system designed to detect abnormal or predetermined system conditions, and take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability. Such action may include changes in demand, generation (MW and Mvar), or system configuration to maintain system stability, acceptable voltage, or power flows. An SPS does not include (a) underfrequency or undervoltage load shedding or (b) fault conditions that must be isolated or (c) out-of-step relaying (not designed as an integral part of an SPS). Also called Remedial Action Scheme.	an automatic protection system designed to detect abnormal or predetermined system conditions, and take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability. Such action may include changes in demand, generation (MW and Mvar), or system configuration to maintain system stability, acceptable voltage, or power flows. A Special Protection System does not include (a) underfrequency or undervoltage Load shedding or (b) fault conditions that must be isolated, or (c) out-of-step relaying (not designed as an integral part of a Special Protection System).**	The SDT is not proposing any alignment revisions at this time. This is because the Project 2010-5.3 drafting team work is still underway and the team may propose changes to this definition. Once the Project 2010-5.3 team finalizes its work, then it will be appropriate to make any necessary alignment changes to the definition of Special Protection System.

Part V: Group 3 recommendations

There are a total of twenty-two (22) Group 3 cross-over terms:

Term 2: Balancing Authority
Term 3: Balancing Authority Area
Term 4: Blackstart Resource
Term 7: Cascading
Term 13: Distribution Provider
Term 14: Element
Term 16: Flowgate
Term 24: Interconnected Operations Service
Term 28: Load Serving Entity
Term 31: Planning Authority
Term 33: Point of Receipt
Term 36: Reactive Power
Term 37: Real Power
Term 38: Reliability Coordinator
Term 41: Reliable Operation
Term 42: Reserve Sharing Group
Term 43: Resource Planner
Term 49: Transmission Customer
Term 50: Transmission Operator
Term 51: Transmission Owner
Term 52: Transmission Planner
Term 54: Transmission Service Provider

The SDT is recommending revisions to all twenty-two (22) of the Group 3 cross-over terms. Below is an overview of the SDT research, assessment, proposed revision(s), and justification for each of the recommendations.

#	Term	Glossary (differences in definition narrative indicated in red)	ROP, Appendix 2 (differences in definition narrative indicated in red)	SDT proposed revisions
2	Balancing Authority	The responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.	the responsible entity that integrates resource plans ahead of time, maintains Load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.**	The SDT is recommending changes to the ROP definition to align with the Glossary. Specifically, the ROP definition uses the defined term for "Load" whereas the Glossary does not. Due to the manner in which the term "Load" is used in the definition, it is not proper to use the defined term. This is because the current ROP definition of Load is, "an end-user device or customer that receives power from the electric system." In the definition narrative of Balancing Authority, use of the word load is not intended to mean an end-user device or customer. Instead, as used in the definition narrative, the term load is actually referring to the ability to maintain demand, or sufficient levels of generation to meet demand. Essentially, it is addressing a measure of energy available to meet the current demand. Additionally, during the course of its work on this project, the SDT reviewed and assessed the quality and correctness of the definition of "Balancing Authority." The SDT believes the current definition is unclear and could be improved by a few minor changes. Specifically, use or application of the term "load-interchange-generation" contained in the definition narrative is unclear. As a result, will draft a SAR proposing to revise the definition of Balancing Authority in order to address this issue. Redline of ROP definition: the responsible entity that integrates resource plans ahead of time, maintains ~~Load~~load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.**
3	Balancing Authority Area	The collection of generation, transmission, and loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains load-resource balance within this area.	the collection of generation, transmission, and Loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains Load-resource balance within this area.**	The SDT is recommending changes to the ROP definition to align with the Glossary. Specifically, the ROP definition uses the defined term for "Load" whereas the Glossary does not. Due to the manner in which the term "Load" is used in the definition, it is not proper to use the defined term. This is because the current ROP definition of Load is, "an end-user device or customer that receives power from the electric system." In the definition narrative of Balancing Authority Area, use of the word load is not intended to mean an end-user device or customer. Instead, as used in the definition narrative, the term load is actually referring to the ability to maintain demand, or sufficient levels of generation to meet demand. Essentially, it is addressing a measure of energy available to meet the current demand. Redline of ROP definition: the collection of generation, transmission, and ~~Loads~~ loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains ~~Load~~load-resource balance within this area.**

4	Blackstart Resource	A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for real and reactive power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.	a generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for Real and Reactive Power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the terms "Real Power" and "Reactive Power" because they are defined terms in the Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for ~~real~~ Real and ~~reactive~~ Reactive ~~power~~ Power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.
7	Cascading	The uncontrolled successive loss of system elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.	the uncontrolled successive loss of System Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the terms "System" and "Elements" because they are defined terms in the Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: The uncontrolled successive loss of ~~system~~ System ~~elements~~ Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.
13	Distribution Provider	Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the Distribution function at any voltage.	the entity that provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the distribution function at any voltage.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Distribution" because it is not a defined term in Glossary (or the ROP). Redline of Glossary term: Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the ~~Distribution~~ distribution function at any voltage.

14	Element	Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components.	any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An Element may be comprised of one or more components.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Element" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An ~~element~~ Element may be comprised of one or more components.
16	Flowgate	1.) A portion of the Transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.	1.) A portion of the transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.**	The SDT is recommending the following changes: (1) Revise the ROP definition to capitalize the word "Transmission." (2) Add the definition of "Transmission" to the ROP. The term is used (and capitalized) in other ROP definition narratives (see, for example, definition of Bulk Electric System). It is appropriate to capitalize it in this particular narrative because its usage in this definition narrative is intended to have the meaning of the defined term. Additionally, as part of the work for this project, the SDT will develop a set of recommendations regarding improvements to the current ROP and Glossary resources. One of the recommendations will be to conduct a comprehensive review of both the ROP and Glossary to identify all instances where a defined term is used, but it is not capitalized (to indicate applicability or use of the definition). The SDT will recommend that for each occurrence of the term, an assessment is conducted to determine whether the term is intended to have the defined meaning; and in the event it is, then the appropriate revisions should be made. Redline of ROP term: 1.) A portion of the ~~transmission~~ Transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.** Add new defined term ("Transmission") to the ROP: "Transmission" means an interconnected group of lines and associated equipment for the movement or transfer of electric energy between points of supply and points at which it is transformed for delivery to customers or is delivered to other electric systems.**

24	Interconnected Operations Service	A service (exclusive of basic energy and transmission services) that is required to support the reliable operation of interconnected Bulk Electric Systems.	a service (exclusive of basic energy and Transmission Services) that is required to support the Reliable Operation of interconnected Bulk Electric Systems.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the terms "Transmission Services" and "Reliable Operation" because they are defined terms in the Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: A service (exclusive of basic energy and ~~transmission~~ Transmission ~~services~~Services) that is required to support the ~~reliable~~ Reliable ~~operation~~ Operation of interconnected Bulk Electric Systems.
28	Load-Serving Entity	Secures energy and transmission service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.	an entity that secures energy and Transmission Service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Transmission Service" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: Secures energy and ~~transmission~~ Transmission ~~service~~ Service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.
31	Planning Authority	The responsible entity that coordinates and integrates transmission facility and service plans, resource plans, and protection systems.	the responsible entity that coordinates and integrates transmission Facilities and service plans, resource plans, and Protection Systems.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the terms "Facilities" and "Protection Systems" because they are defined terms in the Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: The responsible entity that coordinates and integrates transmission ~~facility~~ Facilities and service plans, resource plans, and ~~protection~~ Protection ~~systems~~Systems.
33	Point of Receipt	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a Generator delivers its output.	a location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a generator delivers its output.	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Generator" because it is not a defined term in Glossary or the ROP. Also, because the proposed revisions to the Glossary term will result in alignment of the two definition narratives, the SDT is recommending that a double asterisk (**) is added to the ROP definition.

				Redline of Glossary term: A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a ~~Generator~~ generator delivers its output. Redline of ROP term: a location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a generator delivers its output.**
36	Reactive Power	The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).	the portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive Power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive Power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Power" because "Reactive Power" is a defined term and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive ~~power~~ Power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive ~~power~~ Power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).
37	Real Power	The portion of electricity that supplies energy to the load.	the portion of electricity that supplies energy to the Load.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "load" in the Glossary because it is a defined term and its usage in this definition narrative is intended to have the meaning of the defined term. In the definition narrative of Real Power, use of the word load is intended to mean an end-use device or customer. Redline of Glossary definition: The portion of electricity that supplies energy to the ~~load~~Load.

38	Reliability Coordinator	The entity that is the highest level of authority who is responsible for the reliable operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.	the entity that is the highest level of authority who is responsible for the Reliable Operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Reliable Operation" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity that is the highest level of authority who is responsible for the ~~reliable~~ Reliable ~~operation~~ Operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.
41	Reliable Operation	Operating the elements of the bulk-power system [Bulk-Power System~~]~~ within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements.	operating the Elements of the Bulk Power System within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or Cascading failures of such system will not occur as a result of a sudden disturbance, including a Cyber Security Incident, or unanticipated failure of system Elements.++	The SDT is recommending changes to capitalization in the ROP definition to align with the Glossary and the Federal Power Act. Specifically, the SDT is proposing to remove capitalization of the terms "Elements," "Bulk Power System" "Cascading," and "Cyber Security incident," in order for the definition to remain consistent with the language in the Federal Power Act. Additionally, for both definitions, the SDT is recommending the addition of an explanatory sentence to clarify why defined terms contained in the definition narrative are not capitalized. Redline of Glossary term: Operating the elements of the bulk-power system [Bulk~~-~~ Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.) Redline of ROP term: operating the ~~Elements~~ elements of the bulk-power system [Bulk Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or ~~Cascading~~ cascading failures of such system will not occur as a result of a sudden disturbance, including a ~~Cyber Security Incident~~ cybersecurity incident, or unanticipated failure of system ~~Elements~~elements~~.~~++ (In

				order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)
42	Reserve Sharing Group	A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g., ten minutes). If the transaction is ramped in quicker (e.g., between zero and ten minutes) then, for the purposes of Disturbance Control Performance, the Areas become a Reserve Sharing Group.	a group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g. ten minutes). If the transaction is ramped in quicker, (e.g., between zero and ten minutes), then, for the purposes of disturbance control performance, the areas become a Reserve Sharing Group.**	The SDT is recommending changes to both the Glossary and ROP definitions. Specifically, the SDT is proposing to revise the Glossary definition by removing the capitalization for the terms "Disturbance Control Performance" and "Area" because these are not defined terms. (Note that Disturbance Control Standard and Disturbance are both defined terms). Also, in the ROP definition, the SDT is proposing removal of the unnecessary commas to align with the Glossary definition. Redline of Glossary term: A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (*e.g.*, ten minutes). If the transaction is ramped in quicker (*e.g.*, between zero and ten minutes) then, for the purposes of ~~Disturbance~~ disturbance ~~Control~~ control ~~Performance~~performance, the ~~Areas~~ areas become a Reserve Sharing Group. Redline of ROP term: a group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (*e.g.*~~,~~ ten minutes). If the transaction is ramped in quicker~~,~~ (*e.g.*, between zero and ten minutes)~~,~~ then, for the purposes of disturbance control performance, the areas become a Reserve Sharing Group.**
43	Resource Planner	The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority Area.	the entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority area.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Area" because it is not a defined term in Glossary or the ROP.

				Redline of Glossary term: The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority ~~Area~~area.
49	Transmission Customer	1. Any eligible customer (or its designated agent) that can or does execute a transmission service agreement or can or does receive transmission service. 2. Any of the following responsible entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.	1. any eligible customer (or its designated agent) that can or does execute a Transmission Service agreement or can and does receive Transmission Service. 2. Any of the following ~~responsible~~ entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.**	The SDT is recommending the following changes: (1) Revise the Glossary definition to capitalize the term "Transmission Service" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. (2) Remove the word "responsible" to align with the ROP definition. The word "responsible" was originally included in the ROP definition, but was recently removed by the Risk-Based Registration project. The Glossary should be updated to reflect these recent changes. Redline of Glossary term: 1. Any eligible customer (or its designated agent) that can or does execute a ~~transmission~~ Transmission ~~service~~ Service agreement or can or does receive ~~transmission~~ Transmission ~~service~~Service. 2. Any of the following ~~responsible~~ entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.
50	Transmission Operator	The entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission facilities.	the entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission Facilities.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Facilities" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission ~~facilities~~Facilities.
51	Transmission Owner	The entity that owns and maintains transmission facilities.	the entity that owns and maintains transmission Facilities.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Facilities" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity that owns and maintains transmission ~~facilities~~Facilities.

52	Transmission Planner	The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority Area.	the entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority area.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Area" because it is not a defined term in Glossary or the ROP. Redline of Glossary term: The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority ~~Area~~area.
54	Transmission Service Provider	The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable transmission service agreements.	the entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable Transmission Service agreements.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Transmission Service" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable ~~transmission~~ Transmission ~~service~~ Service agreements.

Part VI: Group 4 recommendations

There are a total of three (3) Group 4 cross-over terms:

Term 20: Interchange Authority

Term 27: Load

Term 34: Protection System

The SDT is recommending revisions to all of the Group 4 cross-over terms. Below is an overview of the SDT research, assessment, proposed revision(s), and justification for each of the recommendations.

Term 20: Interchange Authority

Glossary (differences indicated in red)	ROP, Appendix 2 (differences indicated in red)	SDT proposed revisions
The responsible entity that authorizes implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes.	The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communications of Interchange information for reliability assessment purposes.**	The SDT is recommending errata changes to both the Glossary and ROP definitions, as follows: (1) For the Glossary, add the word "the" to align with the ROP definition. (2) For the ROP, remove the "s" from "communications" to align with the Glossary definition. Redline of Glossary term: The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes. Redline of ROP term: The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication~~s~~ of Interchange information for reliability assessment purposes.**

Term 27: Load

Glossary (differences indicated in red)	ROP, Appendix 2 (differences indicated in red)	SDT proposed revisions
An end-use device or customer that receives power from the electric system.	an end-user device or customer that receives power from the electric system.**	The SDT is recommending an errata change to the ROP definition to align with the Glossary. Specifically, the SDT is proposing to remove the letter "r" from the word "user" in the ROP definition because it was inadvertently included when the definition was added to Appendix 2 of the ROP. On January 26, 2012, NERC filed a petition for approval of various revisions to the ROP, including the addition of new terms to Appendix 2. See, NERC petition. The definition of "Load" was adopted from the Glossary, and marked with a double asterisk (**) to indicate as such. However, the definition included in the NERC petition added the letter "r" to the word "use" which did not (and does not currently) exist in the Glossary definition. For these reasons, the SDT is recommending removal of the "r" from the word "user" in the ROP definition in order to align the Glossary and ROP narratives. Redline of ROP term: an end-user~~r~~ device or customer that receives power from the electric system.**

		Additionally, the SDT notes that during the course of its work on this project, the team reviewed and assessed the quality and correctness of the definition of "Load." The SDT believes the current definition is deficient and could be improved in quality and content. As a result, will draft a SAR proposing to revise the definition in order to address the issues identified by the SDT.

Term 34: Protection System

Glossary (differences indicated in red)	ROP, Appendix 2 (differences indicated in red)	SDT proposed revisions
• Protective relays which respond to electrical quantities, • Communications systems necessary for correct operation of protective functions • Voltage and current sensing devices providing inputs to protective relays, • Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and • Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting device.	protective relays which respond to electrical quantities, communications systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.**	The SDT is recommending an errata change to the ROP definition to align with the Glossary. Specifically, the SDT is proposing to add the word "station" to qualify the Protection System component batteries because it was inadvertently left out of the ROP definition narrative. In 2013, FERC approved the currently effective Glossary definition, which included the qualifier of "station" to the battery term in the definition narrative. However, when the term was adopted in Appendix 2 of the ROP, the qualifier "station" was not included in the definition narrative. Redline of ROP definition: protective relays which respond to electrical quantities, communications systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.**

#	Term	Glossary (differences indicated in red)	ROP, Appendix 2 (differences indicated in red)	GROUP
1	Adjacent Balancing Authority	A Balancing Authority whose Balancing Authority Area is interconnected with another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.	a Balancing Authority Area that is interconnected to another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**	GROUP 1
2	Balancing Authority	The responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.	the responsible entity that integrates resource plans ahead of time, maintains Load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.**	GROUP 3
3	Balancing Authority Area	The collection of generation, transmission, and loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains load-resource balance within this area.	the collection of generation, transmission, and Loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains Load-resource balance within this area.**	GROUP 3
4	Blackstart Resource	A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for real and reactive power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.	a generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for Real and Reactive Power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.**	GROUP 3
5	Bulk Electric System or BES	Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This does not include facilities used in the local distribution of electric energy…	unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This does not include facilities used in the local distribution of electric energy…**	
6	Bulk Power System	Bulk-Power System: A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.	"Bulk Power System" means, depending on the context: (i) Facilities and control systems necessary for operating an interconnected electric energy supply and transmission network (or any portion thereof), and electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy [++]. (ii) Solely for purposes of Appendix 4E, Bulk Electric System.	GROUP 1
7	Cascading	The uncontrolled successive loss of system elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.	the uncontrolled successive loss of System Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.**	GROUP 3

8	Critical Assets	Inactive beginning 3/31/2016: Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the Bulk Electric System.	Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the Bulk Electric System.**	GROUP 2
9	Critical Cyber Assets	Inactive beginning 3/31/2016: Cyber Assets essential to the reliable operation of Critical Assets.	Cyber Assets critical to the reliable operation of Critical Assets.**	GROUP 2
10	Cyber Assets	Inactive beginning 3/31/16: Programmable electronic devices and communication networks including hardware, software, and data. Effective beginning 4/1/2016: Programmable electronic devices, including the hardware, software, and data in those devices.	programmable electronic devices and communication networks including hardware, software, and data.** programmable electronic devices and communication networks including hardware, software, and data.**	GROUP 2
11	Cyber Security Incident	Inactive beginning 3/31/2016: Any malicious act or suspicious event that: • Compromises, or was an attempt to compromise, the Electronic Security Perimeter or Physical Security Perimeter of a Critical Cyber Asset, or, • Disrupts, or was an attempt to disrupt, the operation of a Critical Cyber Asset. Effective beginning 4/1/2016: A malicious act or suspicious event that: • Compromises, or was an attempt to compromise, the Electronic Security Perimeter or Physical Security Perimeter or, • Disrupts, or was an attempt to disrupt, the operation of a BES Cyber System.	"Cyber Security Incident" means any malicious or suspicious event that disrupts, or was an attempt to disrupt, the operation of those programmable electronic devices and communications networks including hardware, software and data that are essential to the Reliable Operation of the Bulk Power System.++	GROUP 2
12	Distribution Factor	The portion of an Interchange Transaction, typically expressed in per unit that flows across a transmission facility (Flowgate).	the portion of an Interchange Transaction, typically expressed in per unit that flows across a transmission facility (Flowgate).**	
13	Distribution Provider	Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the Distribution function at any voltage.	the entity that provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the distribution function at any voltage.**	GROUP 3

14	Element	Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components.	any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An Element may be comprised of one or more components.**	GROUP 2
15	Facility	A set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)	a set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)**	
16	Flowgate	1.) A portion of the Transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.	1.) A portion of the transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.**	GROUP 3
17	Generator Operator	The entity that operates generating unit(s) and performs the functions of supplying energy and Interconnected Operations Services.	the entity that operates generating Facility(ies) and performs the functions of supplying energy and Interconnected Operations Services.**	GROUP 1
18	Generator Owner	Entity that owns and maintains generating units.	an entity that owns and maintains generating Facility(ies).**	GROUP 1
19	Interchange	Energy transfers that cross Balancing Authority boundaries.	energy transfers that cross Balancing Authority boundaries.**	
20	Interchange Authority	The responsible entity that authorizes implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes.	the responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communications of Interchange information for reliability assessment purposes.**	GROUP 4
21	Interchange Distribution Calculator	The mechanism used by Reliability Coordinators in the Eastern Interconnection to calculate the distribution of Interchange Transactions over specific Flowgates. It includes a database of all Interchange Transactions and a matrix of the Distribution Factors for the Eastern Interconnection.	the mechanism used by Reliability Coordinators in the Eastern Interconnection to calculate the distribution of Interchange Transactions over specific Flowgates. It includes a database of all Interchange Transactions and a matrix of the Distribution Factors for the Eastern Interconnection.**	
22	Interchange Schedule	An agreed-upon Interchange Transaction size (megawatts), start and end time, beginning and ending ramp times and rate, and type required for delivery and receipt of power and energy between the Source and Sink Balancing Authorities involved in the transaction.	an agreed-upon Interchange Transaction size (megawatts), start and end time, beginning and ending ramp times and rate, and type required for delivery and receipt of power and energy between the Source and Sink Balancing Authorities involved in the transaction.**	
23	Interchange Transaction	An agreement to transfer energy from a seller to a buyer that crosses one or more Balancing Authority Area boundaries.	an agreement to transfer energy from a seller to a buyer that crosses one or more Balancing Authority Area boundaries.**	

24	Interconnected Operations Service	A service (exclusive of basic energy and transmission services) that is required to support the reliable operation of interconnected Bulk Electric Systems.	a service (exclusive of basic energy and Transmission Services) that is required to support the Reliable Operation of interconnected Bulk Electric Systems.**	GROUP 3
25	Interconnection	Inactive beginning 6/30/16: When capitalized, any one of the three major electric system networks in North America: Eastern, Western, and ERCOT. Effective beginning 7/1/16: When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.	a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++	GROUP 2
26	Interconnection Reliability Operating Limit	A System Operating Limit that, if violated, could lead to instability, uncontrolled separation, or Cascading outages that adversely impact the reliability of the Bulk Electric System.	a System Operating Limit that, if violated, could lead to instability, uncontrolled separation, or Cascading outages that adversely impact the reliability of the Bulk Electric System.**	
27	Load	An end-use device or customer that receives power from the electric system.	an end-user device or customer that receives power from the electric system.**	GROUP 4
28	Load-Serving Entity	Secures energy and transmission service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.	an entity that secures energy and Transmission Service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.**	GROUP 3
29	Net Energy for Load or NEL	Net Balancing Authority Area generation, plus energy received from other Balancing Authority Areas, less energy delivered to Balancing Authority Areas through interchange. It includes Balancing Authority Area losses but excludes energy required for storage at energy storage facilities.	net generation of an electric system plus energy received from others less energy delivered to others through interchange. It includes system losses but excludes energy required for the storage of energy at energy storage facilities.	GROUP 1
30	Open Access Transmission Tariff	Electronic transmission tariff accepted by the U.S. Federal Energy Regulatory Commission requiring the Transmission Service Provider to furnish to all shippers with non-discriminating service comparable to that provided by Transmission Owners to themselves.	an electronic transmission tariff accepted by the U.S. Federal Energy Regulatory Commission requiring the Transmission Service Provider to furnish to all shippers with non-discriminating service comparable to that provided by Transmission Owners to themselves.**	
31	Planning Authority	The responsible entity that coordinates and integrates transmission facility and service plans, resource plans, and protection systems.	the responsible entity that coordinates and integrates transmission Facilities and service plans, resource plans, and Protection Systems.**	GROUP 3
32	Point of Delivery	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction leaves or a Load-Serving Entity receives its energy.	a location that a Transmission Service Provider specifies on its transmission system where an Interchange Transaction leaves or a Load-Serving Entity receives its energy.**	
33	Point of Receipt	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a Generator delivers its output.	a location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a generator delivers its output.	GROUP 3

34	Protection System	Protection System – • Protective relays which respond to electrical quantities, • Communications systems necessary for correct operation of protective functions • Voltage and current sensing devices providing inputs to protective relays, • Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and • Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.	protective relays which respond to electrical quantities, communications systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.**	GROUP 4
35	Purchasing-Selling Entity	The entity that purchases or sells, and takes title to, energy, capacity, and Interconnected Operations Services. Purchasing-Selling Entities may be affiliated or unaffiliated merchants and may or may not own generating facilities.	the entity that purchases, or sells, and takes title to, energy, capacity, and Interconnected Operations Services. Purchasing-Selling Entities may be affiliated or unaffiliated merchants and may or may not own generating facilities.**	
36	Reactive Power	The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).	the portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive Power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive Power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).**	GROUP 3
37	Real Power	The portion of electricity that supplies energy to the load.	the portion of electricity that supplies energy to the Load.**	GROUP 3
38	Reliability Coordinator	The entity that is the highest level of authority who is responsible for the reliable operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.	the entity that is the highest level of authority who is responsible for the Reliable Operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.**	GROUP 3
39	Reliability Coordinator Area	The collection of generation, transmission, and loads within the boundaries of the Reliability Coordinator. Its boundary coincides with one or more Balancing Authority Areas.	the collection of generation, transmission and loads within the boundaries of the Reliability Coordinator. Its boundary coincides with one or more Balancing Authority Areas.**	

40	Reliability Standard	A requirement, approved by the United States Federal Energy Regulatory Commission under this Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk-Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity.	a requirement to provide for Reliable Operation of the Bulk Power System, including without limiting the foregoing, requirements for the operation of existing Bulk Power System Facilities, including cyber security protection, and including the design of planned additions or modifications to such Facilities to the extent necessary for Reliable Operation of the Bulk Power System, but the term does not include any requirement to enlarge Bulk Power System Facilities or to construct new transmission capacity or generation capacity. A Reliability Standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.	GROUP 1
41	Reliable Operation	Operating the elements of the bulk-power system [Bulk-Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements.	operating the Elements of the Bulk Power System within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or Cascading failures of such system will not occur as a result of a sudden disturbance, including a Cyber Security Incident, or unanticipated failure of system Elements.++	GROUP 3
42	Reserve Sharing Group	A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g., ten minutes). If the transaction is ramped in quicker (e.g., between zero and ten minutes) then, for the purposes of Disturbance Control Performance, the Areas become a Reserve Sharing Group.	a group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g. ten minutes). If the transaction is ramped in quicker, (e.g., between zero and ten minutes), then, for the purposes of disturbance control performance, the areas become a Reserve Sharing Group.**	GROUP 3
43	Resource Planner	The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority Area.	the entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority area.**	GROUP 3
44	Sink Balancing Authority	The Balancing Authority in which the load (sink) is located for an Interchange Transaction and any resulting Interchange Schedule.	the Balancing Authority in which the Load (sink) is located for an Interchange Transaction.**	GROUP 1
45	Source Balancing Authority	The Balancing Authority in which the generation (source) is located for an Interchange Transaction and for any resulting Interchange Schedule.	the Balancing Authority in which the generation (source) is located for an Interchange Transaction.**	GROUP 1
46	Special Protection System	An automatic protection system designed to detect abnormal or predetermined system conditions, and	an automatic protection system designed to detect abnormal or predetermined system conditions, and	GROUP 2

		take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability. Such action may include changes in demand, generation (MW and Mvar), or system configuration to maintain system stability, acceptable voltage, or power flows. An SPS does not include (a) underfrequency or undervoltage load shedding or (b) fault conditions that must be isolated or (c) out-of-step relaying (not designed as an integral part of an SPS). Also called Remedial Action Scheme.	take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability. Such action may include changes in demand, generation (MW and Mvar), or system configuration to maintain system stability, acceptable voltage, or power flows. A Special Protection System does not include (a) underfrequency or undervoltage Load shedding or (b) fault conditions that must be isolated, or (c) out-of-step relaying (not designed as an integral part of a Special Protection System).**	
47	System	A combination of generation, transmission, and distribution components.	a combination of generation, transmission and distribution components.**	
48	System Operating Limit	The value (such as MW, MVar, Amperes, Frequency or Volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • Facility Ratings (Applicable pre- and post-Contingency equipment or facility ratings) • Transient Stability Ratings (Applicable pre- and post-Contingency Stability Limits) • Voltage Stability Ratings (Applicable pre- and post-Contingency Voltage Stability) • System Voltage Limits (Applicable pre- and post-Contingency Voltage Limits)	the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria.**	GROUP 1
49	Transmission Customer	1. Any eligible customer (or its designated agent) that can or does execute a transmission service agreement or can or does receive transmission service. 2. Any of the following responsible entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.	1. any eligible customer (or its designated agent) that can or does execute a Transmission Service agreement or can and does receive Transmission Service. 2. Any of the following ~~responsible~~ entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.**	GROUP 3
50	Transmission Operator	The entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission facilities.	the entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission Facilities.**	GROUP 3
51	Transmission Owner	The entity that owns and maintains transmission facilities.	the entity that owns and maintains transmission Facilities.**	GROUP 3
52	Transmission Planner	The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority Area.	the entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority area.**	GROUP 3
53	Transmission Service	Services provided to the Transmission Customer by the Transmission Service Provider to move energy from a Point of Receipt to a Point of Delivery.	services provided to the Transmission Customer by the Transmission Service Provider to move energy from a Point of Receipt to a Point of Delivery.**	

54	Transmission Service Provider	The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable transmission service agreements.	the entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable Transmission Service agreements.**	GROUP 3
55	Wide Area	The entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits.	the entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits.**

#	Cross-Over Term	Glossary (differences indicated in red)	ROP, Appendix 2 (differences indicated in red)	SDT Proposed Revisions
1	Adjacent Balancing Authority	A Balancing Authority whose Balancing Authority Area is interconnected with another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.	a Balancing Authority Area that is interconnected to another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**	The SDT is proposing to revise the ROP definition to align with the Glossary. Redline of ROP definition: a Balancing Authority ~~Area~~ whose Balancing Authority Area ~~that~~ is interconnected ~~with to~~ another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**
2	Balancing Authority	The responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.	the responsible entity that integrates resource plans ahead of time, maintains Load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.**	The SDT is recommending changes to the ROP definition to align with the Glossary. Specifically, the ROP definition uses the defined term for "Load" whereas the Glossary does not. Due to the manner in which the term "Load" is used in the definition, it is not proper to use the defined term. This is because the current ROP definition of Load is, "an end-user device or customer that receives power from the electric system." In the definition narrative of Balancing Authority, use of the word load is not intended to mean an end-user device or customer. Instead, as used in the definition narrative, the term load is actually referring to the ability to maintain demand, or sufficient levels of generation to meet demand. Essentially, it is addressing a measure of energy available to meet the current demand. Additionally, during the course of its work on this project, the SDT reviewed and assessed the quality and correctness of the definition of "Balancing Authority." The SDT believes the current definition is unclear and could be improved by a few minor changes. Specifically, use or application of the term "load-interchange-generation" contained in the definition narrative is unclear. As a result, will draft a SAR proposing to revise the definition of Balancing Authority in order to address this issue. Redline of ROP definition: the responsible entity that integrates resource plans ahead of time, maintains ~~Load~~load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.**

3	Balancing Authority Area	The collection of generation, transmission, and loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains load-resource balance within this area.	the collection of generation, transmission, and Loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains Load-resource balance within this area.**	The SDT is recommending changes to the ROP definition to align with the Glossary. Specifically, the ROP definition uses the defined term for "Load" whereas the Glossary does not. Due to the manner in which the term "Load" is used in the definition, it is not proper to use the defined term. This is because the current ROP definition of Load is, "an end-user device or customer that receives power from the electric system." In the definition narrative of Balancing Authority Area, use of the word load is not intended to mean an end-user device or customer. Instead, as used in the definition narrative, the term load is actually referring to the ability to maintain demand, or sufficient levels of generation to meet demand. Essentially, it is addressing a measure of energy available to meet the current demand. Redline of ROP definition: the collection of generation, transmission, and ~~Loads~~ loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains ~~Load~~load-resource balance within this area.**
4	Blackstart Resource	A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for real and reactive power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.	a generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for Real and Reactive Power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the terms "Real Power" and "Reactive Power" because they are defined terms in the Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for ~~real~~ Real and ~~reactive~~ Reactive ~~power~~ Power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.
5	Bulk Electric System or BES	Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This	unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This	Definitions are aligned.

		does not include facilities used in the local distribution of electric energy…	does not include facilities used in the local distribution of electric energy…**	
6	Bulk Power System	Bulk-Power System: A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.	"Bulk Power System" means, depending on the context: (i) Facilities and control systems necessary for operating an interconnected electric energy supply and transmission network (or any portion thereof), and electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy [++]. (ii) Solely for purposes of Appendix 4E, Bulk Electric System.	The SDT is proposing to revise both definitions as follows: Redline of Glossary definition: Bulk- Power System: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.) Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning. Redline of ROP, Appendix 2 definition: Bulk Power System" means, depending on the context: (i) (A) ~~Facilities~~ facilities and control systems necessary for operating an interconnected electric energy ~~supply and~~ transmission network (or any portion thereof);~~,~~ and (B) electric energy from generation~~g~~ facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy [++]. (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.) ~~-~~Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning. (ii) Solely for purposes of Appendix 4E, Bulk Electric System.
7	Cascading	The uncontrolled successive loss of system elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be	the uncontrolled successive loss of System Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be	The SDT is recommending changes to the Glossary definition to align with the ROP. ~~-~~Specifically, the SDT is proposing to capitalize the terms "System" and "Elements" because they are defined terms in the

		restrained from sequentially spreading beyond an area predetermined by studies.	restrained from sequentially spreading beyond an area predetermined by studies.**	Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: The uncontrolled successive loss of ~~system~~ System ~~elements~~ Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.
8	Critical Assets	Inactive beginning 3/31/2016: Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the Bulk Electric System.	Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the Bulk Electric System.**	The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. The SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.
9	Critical Cyber Assets	Inactive beginning 3/31/2016: Cyber Assets essential to the reliable operation of Critical Assets.	Cyber Assets critical to the reliable operation of Critical Assets.**	The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. The SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.

10	Cyber Assets	Inactive beginning 3/31/16: Programmable electronic devices and communication networks including hardware, software, and data. Effective beginning 4/1/2016: Programmable electronic devices, including the hardware, software, and data in those devices.	programmable electronic devices and communication networks including hardware, software, and data.** programmable electronic devices and communication networks including hardware, software, and data.**	The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. The SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.
11	Cyber Security Incident	Inactive beginning 3/31/2016: Any malicious act or suspicious event that: • Compromises, or was an attempt to compromise, the Electronic Security Perimeter or Physical Security Perimeter of a Critical Cyber Asset, or, • Disrupts, or was an attempt to disrupt, the operation of a Critical Cyber Asset. Effective beginning 4/1/2016: A malicious act or suspicious event that: • Compromises, or was an attempt to compromise, the Electronic Security Perimeter or Physical Security Perimeter or, • Disrupts, or was an attempt to disrupt, the operation of a BES Cyber System.	"Cyber Security Incident" means any malicious or suspicious event that disrupts, or was an attempt to disrupt, the operation of those programmable electronic devices and communications networks including hardware, software and data that are essential to the Reliable Operation of the Bulk Power System.++	The SDT is not proposing revisions to the cross-over terms at this time. This is because the changes that would be necessary to align the terms would necessitate a large number of other changes that are outside the scope of the SAR for this project. The SDT will submit a SAR to address the alignment of terms for all CIP-related definitions. The proposed SAR will include alignment of the defined terms to incorporate the changes to the ROP definitions made through the Version 5 revisions, and also any revisions necessary to provisions of the ROP as a result of proposed changes to the ROP defined terms contained in Appendix 2. The SAR will propose that members of the Project 2008-06 SDT are involved with the revisions to the ROP.
12	Distribution Factor	The portion of an Interchange Transaction, typically expressed in per unit that flows across a transmission facility (Flowgate).	the portion of an Interchange Transaction, typically expressed in per unit that flows across a transmission facility (Flowgate).**	Definitions are aligned.

13	Distribution Provider	Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the Distribution function at any voltage.	the entity that provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the distribution function at any voltage.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Distribution" because it is not a defined term in Glossary (or the ROP). Redline of Glossary term: Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the ~~Distribution~~ distribution function at any voltage.
14	Element	Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components.	any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An Element may be comprised of one or more components.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Element" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An ~~element~~ Element may be comprised of one or more components.
15	Facility	A set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)	a set of electrical equipment that operates as a single Bulk Electric System Element (e.g., a line, a generator, a shunt compensator, transformer, etc.)**	Definitions are aligned.
16	Flowgate	1.) A portion of the Transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities,	1.) A portion of the transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities,	The SDT is recommending the following changes: (1) Revise the ROP definition to capitalize the word "Transmission." (2) Add the definition of "Transmission" to the ROP. The term is used (and capitalized) in other ROP definition narratives (see, for example, definition of Bulk Electric System). It is appropriate to capitalize it in this particular narrative because

		used to analyze the impact of power flows upon the Bulk Electric System.	used to analyze the impact of power flows upon the Bulk Electric System.**	its usage in this definition narrative is intended to have the meaning of the defined term. Additionally, as part of the work for this project, the SDT will develop a set of recommendations regarding improvements to the current ROP and Glossary resources. One of the recommendations will be to conduct a comprehensive review of both the ROP and Glossary to identify all instances where a defined term is used, but it is not capitalized (to indicate applicability or use of the definition). The SDT will recommend that for each occurrence of the term, an assessment is conducted to determine whether the term is intended to have the defined meaning; and in the event it is, then the appropriate revisions should be made. Redline of ROP term: 1.) A portion of the ~~transmission~~ Transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.** Add new defined term ("Transmission") to the ROP: "Transmission" means an interconnected group of lines and associated equipment for the movement or transfer of electric energy between points of supply and points at which it is transformed for delivery to customers or is delivered to other electric systems.**
17	Generator Operator	The entity that operates generating unit(s) and performs the functions of supplying energy and Interconnected Operations Services.	the entity that operates generating Facility(ies) and performs the functions of supplying energy and Interconnected Operations Services.**	The SDT is proposing to revise the Glossary definition to align with the ROP. Redline of Glossary definition: The entity that operates generating Facility(ies) ~~unit(s)~~ and performs the functions of supplying energy and Interconnected Operations Services.

				Additionally, the SDT notes that during the course of its work on this project, the team reviewed and assessed the quality of the definition of "Facility." The SDT believes the clarity and content of the current definition could be improved. As a result, the SDT will draft a SAR proposing to revise the definition in order to address the issues identified by the SDT.
18	Generator Owner	Entity that owns and maintains generating units.	an entity that owns and maintains generating Facility(ies).**	The SDT is proposing to revise the Glossary definition to align with the ROP. Redline of Glossary definition: Entity that owns and maintains generating Facility(ies)~~units~~. Additionally, the SDT notes that during the course of its work on this project, the team reviewed and assessed the quality of the definition of "Facility." The SDT believes the clarity and content of the current definition could be improved. As a result, the SDT will draft a SAR proposing to revise the definition in order to address the issues identified by the SDT.
19	Interchange	Energy transfers that cross Balancing Authority boundaries.	energy transfers that cross Balancing Authority boundaries.**	Definitions are aligned.
20	Interchange Authority	The responsible entity that authorizes implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes.	the responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communications of Interchange information for reliability assessment purposes.**	The SDT is recommending errata changes to both the Glossary and ROP definitions, as follows: (1) For the Glossary, add the word "the" to align with the ROP definition. (2) For the ROP, remove the "s" from "communications" to align with the Glossary definition. Redline of Glossary term: The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes.

				Redline of ROP term: The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communications of Interchange information for reliability assessment purposes.**
21	Interchange Distribution Calculator	The mechanism used by Reliability Coordinators in the Eastern Interconnection to calculate the distribution of Interchange Transactions over specific Flowgates. It includes a database of all Interchange Transactions and a matrix of the Distribution Factors for the Eastern Interconnection.	the mechanism used by Reliability Coordinators in the Eastern Interconnection to calculate the distribution of Interchange Transactions over specific Flowgates. It includes a database of all Interchange Transactions and a matrix of the Distribution Factors for the Eastern Interconnection.**	Definitions are aligned.
22	Interchange Schedule	An agreed-upon Interchange Transaction size (megawatts), start and end time, beginning and ending ramp times and rate, and type required for delivery and receipt of power and energy between the Source and Sink Balancing Authorities involved in the transaction.	an agreed-upon Interchange Transaction size (megawatts), start and end time, beginning and ending ramp times and rate, and type required for delivery and receipt of power and energy between the Source and Sink Balancing Authorities involved in the transaction.**	Definitions are aligned.
23	Interchange Transaction	An agreement to transfer energy from a seller to a buyer that crosses one or more Balancing Authority Area boundaries.	an agreement to transfer energy from a seller to a buyer that crosses one or more Balancing Authority Area boundaries.**	Definitions are aligned.
24	Interconnected Operations Service	A service (exclusive of basic energy and transmission services) that is required to support the reliable operation of interconnected Bulk Electric Systems.	a service (exclusive of basic energy and Transmission Services) that is required to support the Reliable Operation of interconnected Bulk Electric Systems.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the terms "Transmission Services" and "Reliable Operation" because they are defined terms in the Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: A service (exclusive of basic energy and ~~transmission~~ Transmission ~~services~~Services) that is required to support the ~~reliable~~ Reliable ~~operation~~ Operation of interconnected Bulk Electric Systems.

25	Interconnection	Inactive beginning 6/30/16: When capitalized, any one of the three major electric system networks in North America: Eastern, Western, and ERCOT. Effective beginning 7/1/16: When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.	a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++	The SDT is proposing to revise both the Glossary and ROP definitions (effective no earlier than 07/01/16), as follows: Redline of Glossary definition: A geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control. When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec. Redline of ROP definition: a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++ When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.**
26	Interconnection Reliability Operating Limit	A System Operating Limit that, if violated, could lead to instability, uncontrolled separation, or Cascading outages that adversely impact the reliability of the Bulk Electric System.	a System Operating Limit that, if violated, could lead to instability, uncontrolled separation, or Cascading outages that adversely impact the reliability of the Bulk Electric System.**	Definitions are aligned.
27	Load	An end-use device or customer that receives power from the electric system.	an end-user device or customer that receives power from the electric system.**	The SDT is recommending an errata change to the ROP definition to align with the Glossary. Specifically, the SDT is proposing to remove the letter "r" from the word "user" in the ROP definition because it was inadvertently included when the definition was added to Appendix 2 of the ROP. On January 26, 2012, NERC filed a petition for approval of various revisions to the ROP, including the addition of new terms to Appendix 2. (*See*, NERC petition). The definition of "Load" was adopted from the Glossary, and marked with a double asterisk (**) to indicate as such. However, the definition included in the NERC petition added the letter "r" to the word "use" which did not (and does not currently) exist in the Glossary definition. For these reasons, the SDT is recommending

				removal of the "r" from the word "user" in the ROP definition in order to align the Glossary and ROP narratives. Redline of ROP term: an end-user device or customer that receives power from the electric system.** Additionally, the SDT notes that during the course of its work on this project, the team reviewed and assessed the quality and correctness of the definition of "Load." The SDT believes the current definition is deficient and could be improved in quality and content. As a result, will draft a SAR proposing to revise the definition in order to address the issues identified by the SDT.
28	Load-Serving Entity	Secures energy and transmission service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.	an entity that secures energy and Transmission Service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Transmission Service" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: Secures energy and ~~transmission~~ Transmission ~~service~~ Service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.
29	Net Energy for Load or NEL	Net Balancing Authority Area generation, plus energy received from other Balancing Authority Areas, less energy delivered to Balancing Authority Areas through interchange. It includes Balancing Authority Area losses but excludes energy required for storage at energy storage facilities.	net generation of an electric system plus energy received from others less energy delivered to others through interchange. It includes system losses but excludes energy required for the storage of energy at energy storage facilities.	No changes to either ROP or Glossary. The SDT recommends the terms remain unaligned. The differences in the definition narratives are appropriate given the differing uses of the term within the Glossary and ROP.

30	Open Access Transmission Tariff	Electronic transmission tariff accepted by the U.S. Federal Energy Regulatory Commission requiring the Transmission Service Provider to furnish to all shippers with non-discriminating service comparable to that provided by Transmission Owners to themselves.	an electronic transmission tariff accepted by the U.S. Federal Energy Regulatory Commission requiring the Transmission Service Provider to furnish to all shippers with non-discriminating service comparable to that provided by Transmission Owners to themselves.**	Definitions are aligned.
31	Planning Authority	The responsible entity that coordinates and integrates transmission facility and service plans, resource plans, and protection systems.	the responsible entity that coordinates and integrates transmission Facilities and service plans, resource plans, and Protection Systems.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the terms "Facilities" and "Protection Systems" because they are defined terms in the Glossary and their usage in this definition narrative is intended to have the meaning of the defined terms. Redline of Glossary term: The responsible entity that coordinates and integrates transmission ~~facility~~ Facilities and service plans, resource plans, and ~~protection~~ Protection ~~systems~~Systems.
32	Point of Delivery	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction leaves or a Load-Serving Entity receives its energy.	a location that a Transmission Service Provider specifies on its transmission system where an Interchange Transaction leaves or a Load-Serving Entity receives its energy.**	Definitions are aligned.
33	Point of Receipt	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a Generator delivers its output.	a location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a generator delivers its output.	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Generator" because it is not a defined term in Glossary or the ROP. Also, because the proposed revisions to the Glossary term will result in alignment of the two definition narratives, the SDT is recommending that a double asterisk (**) is added to the ROP definition. Redline of Glossary term: A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a ~~Generator~~ generator delivers its output.

				Redline of ROP term: a location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a generator delivers its output.**
34	Protection System	Protection System – • Protective relays which respond to electrical quantities, • Communications systems necessary for correct operation of protective functions • Voltage and current sensing devices providing inputs to protective relays, • Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and • Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.	protective relays which respond to electrical quantities, communications systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.**	The SDT is recommending an errata change to the ROP definition to align with the Glossary. Specifically, the SDT is proposing to add the word "station" to qualify the Protection System component batteries because it was inadvertently left out of the ROP definition narrative. In 2013, FERC approved the currently effective Glossary definition, which included the qualifier of "station" to the battery term in the definition narrative. However, when the term was adopted in Appendix 2 of the ROP, the qualifier "station" was not included in the definition narrative. Redline of ROP definition: protective relays which respond to electrical quantities, communications systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.**
35	Purchasing-Selling Entity	The entity that purchases or sells, and takes title to, energy, capacity, and Interconnected Operations Services. Purchasing-Selling Entities may be affiliated or unaffiliated merchants and may or may not own generating facilities.	the entity that purchases, or sells, and takes title to, energy, capacity, and Interconnected Operations Services. Purchasing-Selling Entities may be affiliated or unaffiliated merchants and may or may not own generating facilities.**	Definitions are aligned.
36	Reactive Power	The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive power must be supplied to most types of magnetic equipment, such as motors and transformers. It	the portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive Power must be supplied to most types of magnetic equipment, such as motors and transformers. It	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Power" because "Reactive Power" is a defined term and its usage in this definition narrative is intended to have the meaning of the defined term.

		also must supply the reactive losses on transmission facilities. Reactive power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).	also must supply the reactive losses on transmission facilities. Reactive Power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).**	Redline of Glossary term: The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive ~~power~~ Power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive ~~power~~ Power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).
37	Real Power	The portion of electricity that supplies energy to the load.	the portion of electricity that supplies energy to the Load.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "load" in the Glossary because it is a defined term and its usage in this definition narrative is intended to have the meaning of the defined term. In the definition narrative of Real Power, use of the word load is intended to mean an end-use device or customer. Redline of Glossary definition: The portion of electricity that supplies energy to the ~~load~~Load.
38	Reliability Coordinator	The entity that is the highest level of authority who is responsible for the reliable operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.	the entity that is the highest level of authority who is responsible for the Reliable Operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Reliable Operation" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity that is the highest level of authority who is responsible for the ~~reliable~~ Reliable ~~operation~~ Operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of

				transmission systems beyond any Transmission Operator's vision.
39	Reliability Coordinator Area	The collection of generation, transmission, and loads within the boundaries of the Reliability Coordinator. Its boundary coincides with one or more Balancing Authority Areas.	the collection of generation, transmission and loads within the boundaries of the Reliability Coordinator. Its boundary coincides with one or more Balancing Authority Areas.**	Definitions are aligned.
40	Reliability Standard	A requirement, approved by the United States Federal Energy Regulatory Commission under this Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk-Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity.	a requirement to provide for Reliable Operation of the Bulk Power System, including without limiting the foregoing, requirements for the operation of existing Bulk Power System Facilities, including cyber security protection, and including the design of planned additions or modifications to such Facilities to the extent necessary for Reliable Operation of the Bulk Power System, but the term does not include any requirement to enlarge Bulk Power System Facilities or to construct new transmission capacity or generation capacity. A Reliability Standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.	The SDT is proposing revisions to both the Glossary and ROP definitions, as follows: Redline of Glossary definition: A requirement, approved by the United States Federal Energy Regulatory Commission under ~~this~~ Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk-Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.) Redline of ROP definition: a requirement, approved by the United States Federal Energy Regulatory Commission under Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System]. ~~, including without limiting the foregoing,~~ The term includes requirements for the operation of existing bulk-power system [Bulk Power System] ~~Facilities~~facilities, including cyber security protection, and ~~including~~ the design of planned additions or

				modifications to such ~~Facilities~~ facilities to the extent necessary for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System], but the term does not include any requirement to enlarge ~~Bulk Power System~~ such ~~Facilities~~ facilities or to construct new transmission capacity or generation capacity.++ (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.) In certain contexts, this term may also refer to a "Reliability Standard" that is in the process of being developed, or not yet approved or recognized by FERC or an applicable governmental authority in other jurisdictions. ~~A Reliability Standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.~~
41	Reliable Operation	Operating the elements of the bulk-power system [Bulk-Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements.	operating the Elements of the Bulk Power System within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or Cascading failures of such system will not occur as a result of a sudden disturbance, including a Cyber Security Incident, or unanticipated failure of system Elements.++	The SDT is recommending changes to capitalization in the ROP definition to align with the Glossary and the Federal Power Act. Specifically, the SDT is proposing to remove capitalization of the terms "Elements," "Bulk Power System" "Cascading," and "Cyber Security incident," in order for the definition to remain consistent with the language in the Federal Power Act. Additionally, for both definitions, the SDT is recommending the addition of an explanatory sentence to clarify why defined terms contained in the definition narrative are not capitalized. Redline of Glossary term: Operating the elements of the bulk-power system [Bulk- Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)

				Redline of ROP term: operating the ~~Elements~~ elements of the bulk-power system [Bulk Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or ~~Cascading~~ cascading failures of such system will not occur as a result of a sudden disturbance, including a ~~Cyber Security Incident~~ cybersecurity incident, or unanticipated failure of system ~~Elements~~elements.++ (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)
42	Reserve Sharing Group	A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g., ten minutes). If the transaction is ramped in quicker (e.g., between zero and ten minutes) then, for the purposes of Disturbance Control Performance, the Areas become a Reserve Sharing Group.	a group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g. ten minutes). If the transaction is ramped in quicker, (e.g., between zero and ten minutes), then, for the purposes of disturbance control performance, the areas become a Reserve Sharing Group.**	The SDT is recommending changes to both the Glossary and ROP definitions. Specifically, the SDT is proposing to revise the Glossary definition by removing the capitalization for the terms "Disturbance Control Performance" and "Area" because these are not defined terms. (Note that Disturbance Control Standard and Disturbance are both defined terms). Also, in the ROP definition, the SDT is proposing removal of the unnecessary commas to align with the Glossary definition. Redline of Glossary term: A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (*e.g.*, ten minutes). If the transaction is ramped in quicker (*e.g.*, between zero and ten minutes) then, for the purposes of ~~Disturbance~~ disturbance ~~Control~~ control ~~Performance~~performance, the ~~Areas~~ areas become a Reserve Sharing Group. Redline of ROP term: a group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply

				operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (*e.g.*, ten minutes). If the transaction is ramped in quicker, (*e.g.*, between zero and ten minutes), then, for the purposes of disturbance control performance, the areas become a Reserve Sharing Group.**
43	Resource Planner	The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority Area.	the entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority area.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Area" because it is not a defined term in Glossary or the ROP. Redline of Glossary term: The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority ~~Area~~area.
44	Sink Balancing Authority	The Balancing Authority in which the load (sink) is located for an Interchange Transaction and any resulting Interchange Schedule.	the Balancing Authority in which the Load (sink) is located for an Interchange Transaction.**	The SDT is proposing to revise the ROP definition to align with the Glossary definition. Redline of ROP definition: the Balancing Authority in which the ~~Load~~ load (sink) is located for an Interchange Transaction and any resulting Interchange Schedule.**
45	Source Balancing Authority	The Balancing Authority in which the generation (source) is located for an Interchange Transaction and for any resulting Interchange Schedule.	the Balancing Authority in which the generation (source) is located for an Interchange Transaction.**	The SDT is proposing to revise the ROP definition to align with the Glossary definition. Redline of ROP definition: the Balancing Authority in which the generation (source) is located for an Interchange Transaction and for any resulting Interchange Schedule.**

46	Special Protection System	An automatic protection system designed to detect abnormal or predetermined system conditions, and take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability. Such action may include changes in demand, generation (MW and Mvar), or system configuration to maintain system stability, acceptable voltage, or power flows. An SPS does not include (a) underfrequency or undervoltage load shedding or (b) fault conditions that must be isolated or (c) out-of-step relaying (not designed as an integral part of an SPS). Also called Remedial Action Scheme.	an automatic protection system designed to detect abnormal or predetermined system conditions, and take corrective actions other than and/or in addition to the isolation of faulted components to maintain system reliability. Such action may include changes in demand, generation (MW and Mvar), or system configuration to maintain system stability, acceptable voltage, or power flows. A Special Protection System does not include (a) underfrequency or undervoltage Load shedding or (b) fault conditions that must be isolated, or (c) out-of-step relaying (not designed as an integral part of a Special Protection System).**	The SDT is not proposing any alignment revisions at this time. This is because the Project 2010-5.3 drafting team work is still underway and the team may propose changes to this definition. Once the Project 2010-5.3 team finalizes its work, then it will be appropriate to make any necessary alignment changes to the definition of Special Protection System.
47	System	A combination of generation, transmission, and distribution components.	a combination of generation, transmission and distribution components.**	Definitions are aligned.
48	System Operating Limit	The value (such as MW, MVar, Amperes, Frequency or Volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • Facility Ratings (Applicable pre- and post-Contingency equipment or facility ratings) • Transient Stability Ratings (Applicable pre- and post-Contingency Stability Limits) • Voltage Stability Ratings (Applicable pre- and post-Contingency Voltage Stability) • System Voltage Limits (Applicable pre- and post-Contingency Voltage Limits)	the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria.**	The SDT is proposing to revise both the Glossary and ROP, as follows: Redline of Glossary definition: The value (such as MW, MVar, ~~A~~amperes, ~~Frequency~~ frequency or ~~Volts~~volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • Facility Ratings (~~Applicable~~ applicable pre- and post-Contingency ~~equipment~~ Equipment Ratings or ~~facility~~ Facility ~~ratings~~Ratings) • ~~Transient~~ transient ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Stability~~ stability ~~Limits~~limits) • ~~Voltage~~ voltage ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Stability~~stability)

				• ~~System~~ system ~~Voltage~~ voltage ~~Limits~~ limits (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Limits~~limits) Redline of ROP definition: the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • facility ratings (applicable pre- and post-contingency equipment ratings or facility ratings) • transient stability ratings (applicable pre- and post-contingency stability limits) • voltage stability ratings (applicable pre- and post-contingency voltage stability) • system voltage limits (applicable pre- and post-contingency voltage limits)**
49	Transmission Customer	1. Any eligible customer (or its designated agent) that can or does execute a transmission service agreement or can or does receive transmission service. 2. Any of the following responsible entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.	1. any eligible customer (or its designated agent) that can or does execute a Transmission Service agreement or can and does receive Transmission Service. 2. Any of the following ~~responsible~~ entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.**	The SDT is recommending the following changes: (1) Revise the Glossary definition to capitalize the term "Transmission Service" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. (2) Remove the word "responsible" to align with the ROP definition. The word "responsible" was originally included in the ROP definition, but was recently removed by the Risk-Based Registration project. The Glossary should be updated to reflect these recent changes. Redline of Glossary term: 1. Any eligible customer (or its designated agent) that can or does execute a ~~transmission~~ Transmission ~~service~~ Service agreement or can or does receive ~~transmission~~ Transmission ~~service~~Service. 2. Any of the following ~~responsible~~ entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.

50	Transmission Operator	The entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission facilities.	the entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission Facilities.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Facilities" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission ~~facilities~~Facilities.
51	Transmission Owner	The entity that owns and maintains transmission facilities.	the entity that owns and maintains transmission Facilities.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Facilities" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity that owns and maintains transmission ~~facilities~~Facilities.
52	Transmission Planner	The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority Area.	the entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority area.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to remove the capitalization from the term "Area" because it is not a defined term in Glossary or the ROP. Redline of Glossary term: The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority ~~Area~~area.
53	Transmission Service	Services provided to the Transmission Customer by the Transmission Service Provider to move energy from a Point of Receipt to a Point of Delivery.	services provided to the Transmission Customer by the Transmission Service Provider to move energy from a Point of Receipt to a Point of Delivery.**	Definitions are aligned.

54	Transmission Service Provider	The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable transmission service agreements.	the entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable Transmission Service agreements.**	The SDT is recommending changes to the Glossary definition to align with the ROP. Specifically, the SDT is proposing to capitalize the term "Transmission Service" because it is a defined term in the Glossary and its usage in this definition narrative is intended to have the meaning of the defined term. Redline of Glossary term: The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable ~~transmission~~ Transmission ~~service~~ Service agreements.
55	Wide Area	The entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits.	the entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits.**	Definitions are aligned.

Proposed Revisions to the Glossary of Terms

Project 2015-04 Alignment of Terms

#	Term	Existing Glossary definition	Redline of Glossary definition
4	Blackstart Resource	A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for real and reactive power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.	A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for ~~real~~ Real and ~~reactive~~ Reactive ~~power~~ Power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.
6	Bulk-Power System	Bulk-Power System: A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.	Bulk~~-~~ Power System: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.) Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning.

7	Cascading	The uncontrolled successive loss of system elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.	The uncontrolled successive loss of ~~system~~ System ~~elements~~ Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.
13	Distribution Provider	Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the Distribution function at any voltage.	Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the ~~Distribution~~ distribution function at any voltage.
14	Element	Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components.	Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An ~~element~~ Element may be comprised of one or more components.
17	Generator Operator	The entity that operates generating unit(s) and performs the functions of supplying energy and Interconnected Operations Services.	The entity that operates generating Facility(ies) ~~unit(s)~~ and performs the functions of supplying energy and Interconnected Operations Services.
18	Generator Owner	Entity that owns and maintains generating units.	Entity that owns and maintains generating Facility(ies)~~units~~.

20	Interchange Authority	The responsible entity that authorizes implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes.	The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes.
24	Interconnected Operations Service	A service (exclusive of basic energy and transmission services) that is required to support the reliable operation of interconnected Bulk Electric Systems.	A service (exclusive of basic energy and ~~transmission~~ Transmission ~~services~~Services) that is required to support the ~~reliable~~ Reliable ~~operation~~ Operation of interconnected Bulk Electric Systems.
25	Interconnection	**Effective beginning 7/1/16**: When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.	A geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control. When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.
28	Load-Serving Entity	Secures energy and transmission service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.	Secures energy and ~~transmission~~ Transmission ~~service~~ Service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.

31	Planning Authority	The responsible entity that coordinates and integrates transmission facility and service plans, resource plans, and protection systems.	The responsible entity that coordinates and integrates transmission ~~facility~~ Facilities and service plans, resource plans, and ~~protection~~ Protection ~~systems~~Systems.
33	Point of Receipt	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a Generator delivers its output.	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a ~~Generator~~ generator delivers its output.
36	Reactive Power	The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).	The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive ~~power~~ Power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive ~~power~~ Power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).
37	Real Power	The portion of electricity that supplies energy to the load.	The portion of electricity that supplies energy to the ~~load~~Load.
38	Reliability Coordinator	The entity that is the highest level of authority who is responsible for the reliable operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis	The entity that is the highest level of authority who is responsible for the ~~reliable~~ Reliable ~~operation~~ Operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis

		and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.	and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.
40	Reliability Standard	A requirement, approved by the United States Federal Energy Regulatory Commission under this Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk-Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk-Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity.	A requirement, approved by the United States Federal Energy Regulatory Commission under ~~this~~ Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk- Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk- Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk- Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)
41	Reliable Operation	Operating the elements of the bulk-power system [Bulk-Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements.	Operating the elements of the bulk-power system [Bulk- Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements. (In order to remain

			consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)
42	Reserve Sharing Group	A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g., ten minutes). If the transaction is ramped in quicker (e.g., between zero and ten minutes) then, for the purposes of Disturbance Control Performance, the Areas become a Reserve Sharing Group.	A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (*e.g.*, ten minutes). If the transaction is ramped in quicker (*e.g.*, between zero and ten minutes) then, for the purposes of ~~Disturbance~~ disturbance ~~Control~~ control ~~Performance~~performance, the ~~Areas~~ areas become a Reserve Sharing Group.
43	Resource Planner	The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority Area.	The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority ~~Area~~area.
48	System Operating Limit	The value (such as MW, MVar, Amperes, Frequency or Volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to:	The value (such as MW, MVar, ~~A~~amperes, ~~Frequency~~ frequency or ~~Volts~~volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to:

		• Facility Ratings (Applicable pre- and post-Contingency equipment or facility ratings) • Transient Stability Ratings (Applicable pre- and post-Contingency Stability Limits) • Voltage Stability Ratings (Applicable pre- and post-Contingency Voltage Stability) • System Voltage Limits (Applicable pre- and post-Contingency Voltage Limits)	• Facility Ratings (~~Applicable~~ applicable pre- and post-Contingency ~~equipment~~ Equipment Ratings or ~~facility~~ Facility ~~ratings~~Ratings) • ~~Transient~~ transient ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Stability~~ stability ~~Limits~~limits) • ~~Voltage~~ voltage ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Stability~~stability) • ~~System~~ system ~~Voltage~~ voltage ~~Limits~~ limits (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Limits~~limits)
49	Transmission Customer	1. Any eligible customer (or its designated agent) that can or does execute a transmission service agreement or can or does receive transmission service. 2. Any of the following responsible entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.	1. Any eligible customer (or its designated agent) that can or does execute a ~~transmission~~ Transmission ~~service~~ Service agreement or can or does receive ~~transmission~~ Transmission ~~service~~Service. 2. Any of the following ~~responsible~~ entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.
50	Transmission Operator	The entity responsible for the reliability of its “local” transmission system, and that operates or directs the operations of the transmission facilities.	The entity responsible for the reliability of its “local” transmission system, and that operates or directs the operations of the transmission ~~facilities~~Facilities.
51	Transmission Owner	The entity that owns and maintains transmission facilities.	The entity that owns and maintains transmission ~~facilities~~Facilities.

52	Transmission Planner	The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority Area.	The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority ~~Area~~area.
54	Transmission Service Provider	The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable transmission service agreements.	The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable ~~transmission~~ Transmission ~~service~~ Service agreements.

Proposed Revisions to Appendix 2 of the Rules of Procedure

Project 2015-04 Alignment of Terms

#	Cross-over Term	Existing Appendix 2, ROP definition	Redline of Appendix 2, ROP definition
1	Adjacent Balancing Authority	a Balancing Authority Area that is interconnected to another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**	a Balancing Authority ~~Area~~ whose Balancing Authority Area ~~that~~ is interconnected with ~~to~~ another Balancing Authority Area either directly or via a multi-party agreement or transmission tariff.**
2	Balancing Authority	the responsible entity that integrates resource plans ahead of time, maintains Load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.**	the responsible entity that integrates resource plans ahead of time, maintains ~~Load~~load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.**
3	Balancing Authority Area	the collection of generation, transmission, and Loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains Load-resource balance within this area.**	the collection of generation, transmission, and ~~Loads~~ loads within the metered boundaries of the Balancing Authority. The Balancing Authority maintains ~~Load~~load-resource balance within this area.**
6	Bulk Power System	"Bulk Power System" means, depending on the context: (i) Facilities and control systems necessary for operating an interconnected electric energy supply and transmission network (or any portion thereof),	Bulk Power System" means, depending on the context: (i) (A) ~~Facilities~~ facilities and control systems necessary for operating an interconnected electric energy ~~supply and~~ transmission network (or any portion thereof)~~;~~ and

		and electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy [++]. (ii) Solely for purposes of Appendix 4E, Bulk Electric System.	(B) electric energy from generation~~g~~ facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy [++].(In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.)~~-~~Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning. (ii) Solely for purposes of Appendix 4E, Bulk Electric System.
16	Flowgate	1.) A portion of the transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.**	1.) A portion of the ~~transmission~~ Transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions. 2.) A mathematical construct, comprised of one or more monitored transmission Facilities and optionally one or more contingency Facilities, used to analyze the impact of power flows upon the Bulk Electric System.** **Add "Transmission" as a new defined term to the ROP:** "Transmission" means an interconnected group of lines and associated equipment for the movement or transfer of electric energy between points of supply and points at which it is transformed for delivery to customers or is delivered to other electric systems.**
20	Interchange Authority	the responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communications of Interchange information for reliability assessment purposes.**	The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication~~s~~ of Interchange information for reliability assessment purposes.**

25	Interconnection	a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++	a geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control.++ When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.**
27	Load	an end-user device or customer that receives power from the electric system.**	an end-use~~r~~ device or customer that receives power from the electric system.**
33	Point of Receipt	a location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a generator delivers its output.	a location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a generator delivers its output.**
34	Protection System	protective relays which respond to electrical quantities, communications systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including batteries, battery chargers, and non-battery-based dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.**	protective relays which respond to electrical quantities, communications systems necessary for correct operation of protective functions, voltage and current sensing devices providing inputs to protective relays, station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.**

40	Reliability Standard	a requirement to provide for Reliable Operation of the Bulk Power System, including without limiting the foregoing, requirements for the operation of existing Bulk Power System Facilities, including cyber security protection, and including the design of planned additions or modifications to such Facilities to the extent necessary for Reliable Operation of the Bulk Power System, but the term does not include any requirement to enlarge Bulk Power System Facilities or to construct new transmission capacity or generation capacity. A Reliability Standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.	a requirement, approved by the United States Federal Energy Regulatory Commission under Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System]. ~~, including without limiting the foregoing,~~ The term includes requirements for the operation of existing bulk-power system [Bulk Power System] ~~Facilities~~facilities, including cyber-security protection, and ~~including~~ the design of planned additions or modifications to such ~~Facilities~~ facilities to the extent necessary for reliable operation [Reliable Operation] of the bulk-power system [Bulk Power System], but the term does not include any requirement to enlarge ~~Bulk Power System~~ such ~~Facilities~~ facilities or to construct new transmission capacity or generation capacity.++ (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.) In certain contexts, this term may also refer to a "Reliability Standard" that is in the process of being developed, or not yet approved or recognized by FERC or an applicable governmental authority in other jurisdictions. ~~A Reliability Standard shall not be effective in the United States until approved by the Federal Energy Regulatory Commission and shall not be effective in other jurisdictions until made or allowed to become effective by the Applicable Governmental Authority.~~
41	Reliable Operation	operating the Elements of the Bulk Power System within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or Cascading failures of such system will not occur as a result of a sudden	operating the ~~Elements~~ elements of the bulk-power system [Bulk Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or ~~Cascading~~ cascading failures of such system will not occur as a result of a sudden disturbance, including a ~~Cyber Security Incident~~ cybersecurity incident, or unanticipated failure of system

		disturbance, including a Cyber Security Incident, or unanticipated failure of system Elements.++	~~Elements~~elements.++ (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)
42	Reserve Sharing Group	a group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (*e.g.* ten minutes). If the transaction is ramped in quicker, (*e.g.*, between zero and ten minutes), then, for the purposes of disturbance control performance, the areas become a Reserve Sharing Group.**	a group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. If the transaction is ramped in quicker~~,~~ (*e.g.*, between zero and ten minutes)~~,~~ then, for the purposes of disturbance control performance, the areas become a Reserve Sharing Group.**
44	Sink Balancing Authority	the Balancing Authority in which the Load (sink) is located for an Interchange Transaction.**	the Balancing Authority in which the ~~Load~~ load (sink) is located for an Interchange Transaction and any resulting Interchange Schedule.**
45	Source Balancing Authority	the Balancing Authority in which the generation (source) is located for an Interchange Transaction.**	the Balancing Authority in which the generation (source) is located for an Interchange Transaction and for any resulting Interchange Schedule.**

48	System Operating Limit	the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria.**	the value (such as MW, Mvar, amperes, frequency or volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • facility ratings (applicable pre- and post-contingency equipment ratings or facility ratings) • transient stability ratings (applicable pre- and post-contingency stability limits) • voltage stability ratings (applicable pre- and post-contingency voltage stability) • system voltage limits (applicable pre- and post-contingency voltage limits).**

Implementation Plan

Project 2015-04 Alignment of Terms

Revisions to Defined Terms in the NERC Glossary of Terms Used in Reliability Standards

The drafting team proposes modifying the following Glossary of Terms definitions:	
<Term>	<Definition>
Blackstart Resource	A generating unit(s) and its associated set of equipment which has the ability to be started without support from the System or is designed to remain energized without connection to the remainder of the System, with the ability to energize a bus, meeting the Transmission Operator's restoration plan needs for ~~real~~ Real and ~~reactive~~ Reactive ~~power~~ Power capability, frequency and voltage control, and that has been included in the Transmission Operator's restoration plan.
Bulk Power System	Bulk~~-~~ Power System: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. (In order to remain consistent with the Federal Power Act [16 U.S.C. 824(o) and 18 C.F.R. 39.1], defined terms contained in this narrative are not capitalized.) Note that the terms "Bulk-Power System" or "Bulk Power System" shall have the same meaning.
Cascading	The uncontrolled successive loss of ~~system~~ System ~~elements~~ Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.
Distribution Provider	Provides and operates the "wires" between the transmission system and the end-use customer. For those end-use customers who are served at transmission voltages, the Transmission Owner also serves as the Distribution Provider. Thus, the Distribution Provider is not defined by a specific voltage, but rather as performing the ~~Distribution~~ distribution function at any voltage.

Element	Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An ~~element~~ Element may be comprised of one or more components.
Generator Operator	The entity that operates generating Facility(ies) ~~unit(s)~~ and performs the functions of supplying energy and Interconnected Operations Services.
Generator Owner	Entity that owns and maintains generating Facility(ies)~~units~~.
Interchange Authority	The responsible entity that authorizes the implementation of valid and balanced Interchange Schedules between Balancing Authority Areas, and ensures communication of Interchange information for reliability assessment purposes.
Interconnected Operations Service	A service (exclusive of basic energy and ~~transmission~~ Transmission ~~services~~Services) that is required to support the ~~reliable~~ Reliable ~~operation~~ Operation of interconnected Bulk Electric Systems.
Interconnection	A geographic area in which the operation of Bulk Power System components is synchronized such that the failure of one or more of such components may adversely affect the ability of the operators of other components within the system to maintain Reliable Operation of the Facilities within their control. When capitalized, any one of the four major electric system networks in North America: Eastern, Western, ERCOT and Quebec.
Load-Serving Entity	Secures energy and ~~transmission~~ Transmission ~~service~~ Service (and related Interconnected Operations Services) to serve the electrical demand and energy requirements of its end-use customers.
Planning Authority	The responsible entity that coordinates and integrates transmission ~~facility~~ Facilities and service plans, resource plans, and ~~protection~~ Protection ~~systems~~Systems.

Point of Receipt	A location that the Transmission Service Provider specifies on its transmission system where an Interchange Transaction enters or a ~~Generator~~ generator delivers its output.
Reactive Power	The portion of electricity that establishes and sustains the electric and magnetic fields of alternating-current equipment. Reactive ~~power~~ Power must be supplied to most types of magnetic equipment, such as motors and transformers. It also must supply the reactive losses on transmission facilities. Reactive ~~power~~ Power is provided by generators, synchronous condensers, or electrostatic equipment such as capacitors and directly influences electric system voltage. It is usually expressed in kilovars (kvar) or megavars (Mvar).
Real Power	The portion of electricity that supplies energy to the ~~load~~Load.
Reliability Coordinator	The entity that is the highest level of authority who is responsible for the ~~reliable~~ Reliable ~~operation~~ Operation of the Bulk Electric System, has the Wide Area view of the Bulk Electric System, and has the operating tools, processes and procedures, including the authority to prevent or mitigate emergency operating situations in both next-day analysis and real-time operations. The Reliability Coordinator has the purview that is broad enough to enable the calculation of Interconnection Reliability Operating Limits, which may be based on the operating parameters of transmission systems beyond any Transmission Operator's vision.
Reliability Standard	A requirement, approved by the United States Federal Energy Regulatory Commission under ~~this~~ Section 215 of the Federal Power Act, or approved or recognized by an applicable governmental authority in other jurisdictions, to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk~~-~~ Power System]. The term includes requirements for the operation of existing bulk-power system [Bulk~~-~~ Power System] facilities, including cybersecurity protection, and the design of planned additions or modifications to such facilities to the extent necessary to provide for reliable operation [Reliable Operation] of the bulk-power system [Bulk~~-~~ Power System], but the term does not include any requirement to enlarge such facilities or to construct new transmission capacity or generation capacity. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)

Reliable Operation	Operating the elements of the bulk-power system [Bulk- Power System] within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure of system elements. (In order to remain consistent with the Federal Power Act, defined terms contained in this narrative are not capitalized.)
Reserve Sharing Group	A group whose members consist of two or more Balancing Authorities that collectively maintain, allocate, and supply operating reserves required for each Balancing Authority's use in recovering from contingencies within the group. Scheduling energy from an Adjacent Balancing Authority to aid recovery need not constitute reserve sharing provided the transaction is ramped in over a period the supplying party could reasonably be expected to load generation in (e.g., ten minutes). If the transaction is ramped in quicker (e.g., between zero and ten minutes) then, for the purposes of ~~Disturbance~~ disturbance ~~Control~~ control ~~Performance~~performance, the ~~Areas~~ areas become a Reserve Sharing Group.
Resource Planner	The entity that develops a long-term (generally one year and beyond) plan for the resource adequacy of specific loads (customer demand and energy requirements) within a Planning Authority ~~Area~~area.
System Operating Limit	The value (such as MW, MVar, ~~A~~amperes, ~~Frequency~~ frequency or ~~Volts~~volts) that satisfies the most limiting of the prescribed operating criteria for a specified system configuration to ensure operation within acceptable reliability criteria. System Operating Limits are based upon certain operating criteria. These include, but are not limited to: • Facility Ratings (~~Applicable~~ applicable pre- and post-Contingency ~~equipment~~ Equipment Ratings or ~~facility~~ Facility ~~ratings~~Ratings) • ~~Transient~~ transient ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Stability~~ stability ~~Limits~~limits) • ~~Voltage~~ voltage ~~Stability~~ stability ~~Ratings~~ ratings (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Stability~~stability) • ~~System~~ system ~~Voltage~~ voltage ~~Limits~~ limits (~~Applicable~~ applicable pre- and post-Contingency ~~Voltage~~ voltage ~~Limits~~limits)

Transmission Customer	1. Any eligible customer (or its designated agent) that can or does execute a ~~transmission~~ Transmission ~~service~~ Service agreement or can or does receive ~~transmission~~ Transmission ~~service~~Service. 2. Any of the following ~~responsible~~ entities: Generator Owner, Load-Serving Entity, or Purchasing-Selling Entity.
Transmission Operator	The entity responsible for the reliability of its "local" transmission system, and that operates or directs the operations of the transmission ~~facilities~~Facilities.
Transmission Owner	The entity that owns and maintains transmission ~~facilities~~Facilities.
Transmission Planner	The entity that develops a long-term (generally one year and beyond) plan for the reliability (adequacy) of the interconnected bulk electric transmission systems within its portion of the Planning Authority ~~Area~~area.
Transmission Service Provider	The entity that administers the transmission tariff and provides Transmission Service to Transmission Customers under applicable ~~transmission~~ Transmission ~~service~~ Service agreements.

Requested Retirements

- None

Prerequisite Approvals

It is requested that all proposed changes to the definitions in the NERC Rules of Procedure are approved contemporaneously with the proposed revisions to the Glossary of Terms. Additionally, it is requested that the proposed revisions do not take effect until the first day of the first calendar quarter beyond the date that the definitions are approved by applicable regulatory authorities, but no earlier than 07/01/2016.

Background

The purpose of Project 2015-04 – Alignment of Terms is to align the defined terms found in the NERC Glossary of Terms found in Reliability Standards and the Rules of Procedure. This project is necessary because currently there are defined terms that appear in both the Glossary and ROP that are inconsistent in substance and form. This causes industry confusion and may lead to inconsistent interpretation or application of the meaning of a term. Consistent definitions will enhance reliability because owners, users and operators of the BES, along with the ERO Enterprise, will have a clear and consistent understanding of the terminology used in the NERC Reliability Standards and ROP. Of the fifty-five (55) cross-over terms, forty (40) contain inconsistencies or differences in the definition narratives. To achieve consistency and alignment of these cross-over terms, the SDT is proposing revisions to twenty-six (26) Glossary terms and sixteen (16) ROP terms.

Effective Date

The definitions shall be added to the NERC Glossary of Terms used in Reliability Standards effective on the first day of the first calendar quarter beyond the date that the definitions are approved by applicable regulatory authorities, but no earlier than 07/01/2016, or in those jurisdictions where regulatory approval is not required, the definitions become effective on the first day of the first calendar quarter beyond the date this standard is approved by the NERC Board of Trustees, but no earlier than 07/01/2016, or as otherwise made effective pursuant to the laws applicable to such governmental authorities.

Alignment of PRC-005 Compliance Dates

I. PRC-005 Compliance Issue and Proposal to Align Compliance Dates

Since the approval of PRC-005-2, which is currently mandatory and enforceable, a number of standards development projects have resulted in either including or excluding devices from the scope of PRC-005. Currently, there are eight approved or currently proposed PRC-005 versions, and each Version comes with a separate implementation schedule. Depending on the type of device and specific requirement in some of the PRC-005 versions, the implementation is divided into phases, requiring registered entities to gradually ensure compliance of a percentage of their devices until they reach 100% compliance.

Versions -3, -4, and -6 will require three consecutive updates to the registered entities' Protection System Maintenance Programs (PSMP), which is expected to be a time-consuming task for many. Based on the implementation plans for these three Versions, the required PSMP updates would have to be completed within a year to 18 months. According to the PRC-005 drafting team, which represents various industry members, this short period of time for review and identification of all assets subject to the revised PRC-005 Versions could lead to errors and misidentification of devices. Further, the existence of eight implementation plans could lead to misinterpretations and inconsistencies in the compliance and auditing practices throughout the ERO Enterprise.

To address this compliance issue, the PRC-005 drafting team requested that NERC align the effective dates of all outstanding PRC-005 Versions, thus simplifying the implementation schedule for this Reliability Standard. In response to the drafting team's request, NERC plans to petition the Federal Energy Regulatory Commission (FERC) to delay the implementation of PRC-005-3 and have PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4, PRC-005-5, and PRC-005-6 all become effective on the same date. NERC is also proposing that the implementation of PRC-005-2(i) is aligned with the currently effective PRC-005-2. The phased implementation approach will remain but the effective dates for each phase will align across all applicable Versions.

This proposal is reflected in the implementation plan for PRC-005-6. If supported by industry members, the implementation plan will be included in the PRC-005-6 petition to be filed with FERC for review.

II. PRC-005 Versions Overview

The draft PRC-005-6 incorporates all revisions made to PRC-005-2 as a result of the development of PRC-005-2(i), PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4, and PRC-005-5, and PRC-005-6. Version 3 added Automatic Reclosing devices; Versions 2(i), 3(i), and -5 exclude individual dispersed generation resources from the applicability of the Standard; Versions 2(ii) and 3(ii) replace the term "Special Protection System" with the term "Remedial Action Scheme"; Version 4 added Sudden Pressure Relays; and Version 6 will add supervisory relays and exclude individual dispersed generation resources from the applicability of this Reliability Standard.

From this list of all PRC-005 Versions, Version 3 is approved by FERC; PRC-005-2(i), PRC-005-2(ii), PRC-005-3(i), PRC-005-3(ii), and PRC-005-4 are pending regulatory approval; PRC-005-5 has not yet been filed for approval with FERC; and PRC-005-6 is currently under development.

III. Impact on the Reliability of the Bulk Power System and on Compliance with PRC-005

Based on the implementation schedule for the FERC-approved PRC-005-3 and estimated approval and effective dates for the remaining Versions, the delay in the implementation of PRC-005-3 created by this proposal is anticipated to be approximately one year.

The proposed changes described here and in the proposed PRC-005-6 implementation plan will not affect the immediate implementation of Versions 2(i), 3(i), and -5. These Versions exclude certain dispersed generation resources from the definition of Bulk Electric System, and from the applicability of PRC-005. Thus, registered entities that own and operate dispersed generation resources will remain unaffected by the proposed changes.

PRC-005-2(ii) and PRC-005-3(ii) reflect enhancements to the NERC Glossary of Terms related to Special Protection Systems and Remedial Action Schemes. While alignment between the standards and the Glossary of Terms is important, potential delays in this alignment would not present a risk to the reliability of the BPS. The petition requesting changes to PRC-005-2(ii) and PRC-005-3(ii) is pending and its review will likely be delayed until the Commission reviews the petition for PRC-010-1 related to Under-Voltage Load Shedding Program. Finally, the anticipated changes related to Remedial Action Schemes are minor in nature and are unlikely to introduce an actual reliability risk.

Because the Automatic Reclosing devices and Sudden Pressure Relays brought in by Versions -3 and -4 are limited in scope, a potential delay in the implementation of these Versions of PRC-005 is also unlikely to increase risk to the BPS. Many of these devices are already monitored by industry in anticipation of the upcoming compliance requirements, but may not be specifically included in the registered entities' PSMPs at this time.

IV. Benefits to Registered Entities

The proposal aims to simplify the compliance efforts of all registered entities subject to PRC-005 and give industry additional time to comply with Versions -3, -4, and -6, which require PSMP updates. Having PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4, and PRC-005-5, PRC-005-6 become effective at the same time minimizes the possibility of misinterpretations of each Version and associated compliance obligations, thus limiting the compliance risk for registered entities. In addition, the proposed changes will not affect the anticipated exclusion of certain dispersed generation resources from the applicability of the standard.

To further facilitate compliance, NERC plans to use the additional time until PRC-005-6 becomes effective to conduct outreach and provide training to ensure that registered entities are well aware and prepared to meet their obligations under the various PRC-005 Versions.

Effective Date Information

Table 1 provides information regarding each version of the PRC-005 standard.

Table 1: PRC-005 Effective Date Information		
Standard	**Effective Date[1]**	**Comments**
PRC-005-2	April 1, 2015	
PRC-005-2(i)	May 29, 2015	Proposed effective with version 2, which will be immediately following FERC Approval.
PRC-005-2(ii)	Filed and Pending Regulatory Approval	Proposed to be deferred until version 6 effective date.[2]
PRC-005-3	April 1, 2016	Proposed to be deferred until version 6 effective date.
PRC-005-3(i)	April 1, 2016	Proposed to be deferred until version 6 effective date.
PRC-005-3(ii)	Filed and Pending Regulatory Approval	Proposed to be deferred until version 6 effective date.
PRC-005-4	Filed and Pending Regulatory Approval	Proposed to be deferred until version 6 effective date.
PRC-005-5	Pending Regulatory Filing	Proposed to be deferred until version 6 effective date.
PRC-005-6	Pending Regulatory Filing	TBD

[1] The effective date listed is the start date of when the standard becomes effective. This does not include the phased in approach.

[2] This is based on when FERC approves PRC-005-6, which could be from three (3) months to one (1) year.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Violation Risk Factor and Violation Severity Level Justifications

Project 2007-17.4 PRC-005-6
Protection System, Automatic Reclosing and Sudden Pressure Relaying Maintenance

Violation Risk Factor and Violation Severity Level Justifications

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-005-6~~2~~ - Protection System, Automatic Reclosing and Sudden Pressure Relaying Maintenance.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

The Protection System Maintenance and Testing Standard Drafting Team applied the following NERC criteria and FERC Guidelines when proposing VRFs and VSLs for the requirements under this project:

NERC Criteria – VRFs

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the

preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

FERC VRF Guidelines

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) — Consistency among Reliability Standards

The Commission expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the VRF Level

Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

PRC-005~~-X~~-6 Protection System, Automatic Reclosing and Sudden Pressure Relaying Maintenance is a revision of PRC-005-3 Protection System and Automatic Reclosing Maintenance with the stated purpose: To document and implement programs for the maintenance of all Protection Systems, Automatic Reclosing, and Sudden Pressure Relaying affecting the reliability of the Bulk Electric System (BES) so that they are kept in working order.

PRC-005~~-X~~-6 has five (5) requirements that address the inclusion of Sudden Pressure Relaying. A Table of minimum maintenance activities and maximum maintenance intervals for Sudden Pressure Relaying has been added to PRC-005-3 to address FERC's directives from Order 758. The revised standard requires that entities develop an appropriate Protection System Maintenance Program (PSMP), that they implement their PSMP, and that, in the event they are unable to restore Sudden Pressure Relaying Components to proper working order while performing maintenance, they initiate the follow-up activities necessary to resolve those maintenance issues.

The requirements of PRC-005~~-X~~-6 map one-to-one with the requirements of PRC-005-3. The drafting team did not revise the VRFs for the requirements of PRC-005-3.

PRC-005~~-X~~-6 Requirements R1 and R2 are related to developing and documenting a Protection System Maintenance Program. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violations of these requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

PRC-005-~~6~~4 Requirements R3 and R4 are related to implementation of the Protection System Maintenance Program. The SDT determined that the assignment of a VRF of High was consistent with the NERC criteria that that violation of these requirements could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are assigned a VRF of High.

PRC-005-~~X~~-6 Requirement R5 relates to the initiation of resolution of unresolved maintenance issues, which describe situations where an entity was unable to restore a Component to proper working order during the performance of the maintenance activity. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violation of this requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

NERC Criteria - VSLs

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on the guidelines shown in the table below:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital Component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC Order on VSLs

In its June 19, 2008 Order on VSLs, FERC indicated it would use the following four guidelines for determining whether to approve VSLs:

Guideline 1: VSL Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

- Compare the VSLs to any prior Levels of Non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when Levels of Non-compliance were used.

Guideline 2: VSL Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

- Guideline 2a: A violation of a "binary" type requirement must be a "Severe" VSL.
- Guideline 2b: Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: VSL Assignment Should Be Consistent with the Corresponding Requirement

- VSLs should not expand on what is required in the requirement.

Guideline 4: VSL Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

- . . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF and VSL Justifications

VRF and VSL Justifications – PRC-005-~~X~~-6, R1	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no sub-requirements so only one VRF was assigned. The requirement utilizes Parts to identify the items to be included within a Protection System Maintenance Program. The VRF for this requirement is consistent with others in the standard with regard to relative risk; therefore, there is no conflict.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-~~X~~-6 Requirement R1.

VRF and VSL Justifications – PRC-005~~-X~~-6, R1	
Proposed VRF	**Medium**
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.

Proposed VSL – PRC-005~~-X~~-6, R1			
Lower	**Moderate**	**High**	**Severe**
The entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The entity's PSMP failed to specify whether three Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1). OR	The entity failed to establish a PSMP. OR The entity's PSMP failed to specify whether four or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1).

Proposed VSL – PRC-005-~~X~~-6, R1			
Lower	**Moderate**	**High**	**Severe**
		The entity's PSMP failed to include the applicable monitoring attributes applied to each Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-~~2~~3, and Table 5where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Components. (Part 1.2).	OR The entity's PSMP failed to include applicable station batteries in a time-based program (Part 1.1)

Proposed VRF	**Medium**
NERC VRF Discussion	Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only requirement within approved Standards, PRC-004-2a Requirements R1 and R2 contain a similar requirement and is assigned a HIGH VRF. However, these requirements contain several subparts, and the VRF must address the most egregious risk related to these subparts, and a comparison to these requirements may be irrelevant. PRC-022-1 Requirement R1.5 contains only a similar requirement, and is assigned a MEDIUM VRF. FAC-003-2 Requirement R5 contains only a similar requirement, and is assigned a MEDIUM VRF.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component could directly affect the electrical state or the capability of the bulk power system.

Violation Risk Factor and Violation Severity Level Justifications

Project 2007-17.4 PRC-005-6
Protection System, Automatic Reclosing and Sudden Pressure Relaying Maintenance

Violation Risk Factor and Violation Severity Level Justifications

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in PRC-005-6 - Protection System, Automatic Reclosing and Sudden Pressure Relaying Maintenance.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

The Protection System Maintenance and Testing Standard Drafting Team applied the following NERC criteria and FERC Guidelines when proposing VRFs and VSLs for the requirements under this project:

NERC Criteria – VRFs

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the

preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

FERC VRF Guidelines

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) — Consistency among Reliability Standards

The Commission expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the VRF Level

Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

PRC-005-6 Protection System, Automatic Reclosing and Sudden Pressure Relaying Maintenance is a revision of PRC-005-3 Protection System and Automatic Reclosing Maintenance with the stated purpose: To document and implement programs for the maintenance of all Protection Systems, Automatic Reclosing, and Sudden Pressure Relaying affecting the reliability of the Bulk Electric System (BES) so that they are kept in working order.

PRC-005-6 has five (5) requirements that address the inclusion of Sudden Pressure Relaying. A Table of minimum maintenance activities and maximum maintenance intervals for Sudden Pressure Relaying has been added to PRC-005-3 to address FERC's directives from Order 758. The revised standard requires that entities develop an appropriate Protection System Maintenance Program (PSMP), that they implement their PSMP, and that, in the event they are unable to restore Sudden Pressure Relaying Components to proper working order while performing maintenance, they initiate the follow-up activities necessary to resolve those maintenance issues.

The requirements of PRC-005-6 map one-to-one with the requirements of PRC-005-3. The drafting team did not revise the VRFs for the requirements of PRC-005-3.

PRC-005-6 Requirements R1 and R2 are related to developing and documenting a Protection System Maintenance Program. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violations of these requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

PRC-005-6 Requirements R3 and R4 are related to implementation of the Protection System Maintenance Program. The SDT determined that the assignment of a VRF of High was consistent with the NERC criteria that that violation of these requirements could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are assigned a VRF of High.

PRC-005-6 Requirement R5 relates to the initiation of resolution of unresolved maintenance issues, which describe situations where an entity was unable to restore a Component to proper working order during the performance of the maintenance activity. The Standard Drafting Team determined that the assignment of a VRF of Medium was consistent with the NERC criteria that violation of this requirements could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system but are unlikely to lead to bulk electric system instability, separation, or cascading failures. Additionally, a review of the body of existing NERC Standards with approved VRFs revealed that requirements with similar reliability objectives in other standards are largely assigned a VRF of Medium.

NERC Criteria - VSLs

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on the guidelines shown in the table below:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital Component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC Order on VSLs

In its June 19, 2008 Order on VSLs, FERC indicated it would use the following four guidelines for determining whether to approve VSLs:

Guideline 1: VSL Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

- Compare the VSLs to any prior Levels of Non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when Levels of Non-compliance were used.

Guideline 2: VSL Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

- Guideline 2a: A violation of a "binary" type requirement must be a "Severe" VSL.
- Guideline 2b: Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline 3: VSL Assignment Should Be Consistent with the Corresponding Requirement

- VSLs should not expand on what is required in the requirement.

Guideline 4: VSL Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

- . . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF and VSL Justifications

VRF and VSL Justifications – PRC-005-6, R1	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no sub-requirements so only one VRF was assigned. The requirement utilizes Parts to identify the items to be included within a Protection System Maintenance Program. The VRF for this requirement is consistent with others in the standard with regard to relative risk; therefore, there is no conflict.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-6 Requirement R1.

VRF and VSL Justifications – PRC-005-6, R1			
Proposed VRF	**Medium**		
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to establish a Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.		
FERC VRF G5 Discussion	Guideline 5- Treatment of Requirements that Co-mingle More than One Obligation: This requirement establishes a single risk-level, and the assigned VRF is consistent with that risk level.		
Proposed VSL – PRC-005-6, R1			
Lower	**Moderate**	**High**	**Severe**
The entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1)	The entity's PSMP failed to specify whether three Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1). OR	The entity failed to establish a PSMP. OR The entity's PSMP failed to specify whether four or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1).

Proposed VSL – PRC-005-6, R1			
Lower	**Moderate**	**High**	**Severe**
		The entity's PSMP failed to include the applicable monitoring attributes applied to each Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3, and Table 5where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Components. (Part 1.2).	OR The entity's PSMP failed to include applicable station batteries in a time-based program (Part 1.1)

VRF and VSL Justifications – PRC-005-6, R1	
NERC VSL Guidelines	Meets NERC's VSL Guidelines—There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.
FERC VSL G1 VSL Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	This VSL is consistent with the current VSLs associated with the existing requirements of the standards being replaced by this proposed standard.
FERC VSL G2 VSL Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single VSL Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: VSL Assignments that Contain Ambiguous Language	Guideline 2a: N/A Guideline 2b: The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.

VRF and VSL Justifications – PRC-005-6, R1	
FERC VSL G3 VSL Assignment Should Be Consistent with the Corresponding Requirement	The proposed VSL uses similar terminology to that used in the associated requirement, and is therefore consistent with the requirement.
FERC VSL G4 VSL Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations	The VSL is based on a single violation and not cumulative violations.

VRF and VSL Justifications – PRC-005-6, R2	
Proposed VRF	**Medium**
NERC VRF Discussion	Failure to properly establish a performance-based Protection System Maintenance Program (PSMP) for Protection Systems designed to provide protection for BES Element(s) could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to properly establish a performance-based Protection System Maintenance Program (PSMP) for Protection Systems will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The SDT has determined that there is no consistency among existing approved Standards relative to requirements of this nature. The SDT has assigned a MEDIUM VRF, which is consistent with recent FERC guidance on FAC-008-3 Requirement R2 and FAC-013-2 Requirement R1, which are similar in nature to PRC-005-6 Requirement R1.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to properly establish a performance-based Protection System Maintenance Program (PSMP) for.

NERC VRF Discussion	Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component could directly affect the electrical state or the capability of the bulk power system. However, violation of this requirement is unlikely to lead to bulk power system instability, separation, or cascading failures. The applicable entities are always responsible for maintaining the reliability of the bulk power system regardless of the situation. This VRF emphasizes the risk to system performance that results from mal-performing Protection System Components. Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component will not, by itself, lead to instability, separation, or cascading failures. Thus, the requirement meets NERC's criteria for a Medium VRF.
FERC VRF G1 Discussion	Guideline 1- Consistency w/ Blackout Report: N/A
FERC VRF G2 Discussion	Guideline 2- Consistency within a Reliability Standard: The requirement has no subpart(s); therefore, only one VRF was assigned and no conflict(s) exist.
FERC VRF G3 Discussion	Guideline 3- Consistency among Reliability Standards: The only requirement within approved Standards, PRC-004-2a Requirements R1 and R2 contain a similar requirement and is assigned a HIGH VRF. However, these requirements contain several subparts, and the VRF must address the most egregious risk related to these subparts, and a comparison to these requirements may be irrelevant. PRC-022-1 Requirement R1.5 contains only a similar requirement, and is assigned a MEDIUM VRF. FAC-003-2 Requirement R5 contains only a similar requirement, and is assigned a MEDIUM VRF.
FERC VRF G4 Discussion	Guideline 4- Consistency with NERC Definitions of VRFs: Failure to initiate resolution of an unresolved maintenance issue for a Protection System Component could directly affect the electrical state or the capability of the bulk power system.

VRF and VSL Justifications – PRC-005-6, R5

1. Introduction and Summary

Note: This supplementary reference for PRC-005-4 is neither mandatory nor enforceable.

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and Canada and address various aspects of maintenance and testing of Protection and Control Systems.

These standards are:

PRC-005-1b — Transmission and Generation Protection System Maintenance and Testing

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

PRC-011-0 — UVLS System Maintenance and Testing

PRC-017-0 — Special Protection System Maintenance and Testing

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-3 will replace PRC-005-2 which combined and replaced PRC-005, PRC-008, PRC-011 and PRC-017. PRC-005-3 adds Automatic Reclosing to PRC-005-2. PRC-005-2 addressed these directed modifications and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

FERC Order 758 further directed that maintenance of reclosing relays and sudden pressure relays that affect the reliable operation of the Bulk Power System be addressed. PRC-005-3 addresses this directive regarding reclosing relays, and, when approved, will supersede PRC-005-2. PRC-005-4 addresses this directive regarding sudden pressure relays and, when approved, will supersede PRC-005-3.

This document augments the Supplementary Reference and FAQ previously developed for PRC-005-2 by including discussion relevant to Automatic Reclosing added in PRC-005-3 and Sudden Pressure Relaying in PRC-005-4.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a Fault or other power system problem requires that they operate to protect power system Elements, or even the entire Bulk Electric System (BES). Lacking Faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A Misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide-area Disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components, such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries, which are an important part of the station dc supply, are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear Faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-4 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications Systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the Element is a BES Element, then the Protection System protecting that Element should then be included within this standard. If there is regional variation to the definition, then there will be a corresponding regional variation to the Protection Systems that fall under this standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the standard language should simply be applicable to Protection Systems for BES Elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC Glossary of Terms for the present, in-force definition. See the applicable Regional Reliability Organization for any applicable allowed variations.

While this standard will undergo revisions in the future, this standard will not attempt to keep up with revisions to the NERC definition of BES, but, rather, simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GOs and TOs have equipment that is BES equipment. The standard brings in Distribution Providers (DP) because, depending on the station configuration of a particular substation, there may be

Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-4 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

PRC-005-2 replaced the existing PRC-005, PRC-008, PRC-011 and PRC-017. Much of the original intent of those standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example, the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as stipulated in any requirement in this standard.

Additionally, since PRC-005-2 replaced PRC-011, it will be important to make the distinction between under-voltage Protection Systems that protect individual Loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 is now applicable under PRC-005-2. An example of an under-voltage load-shedding scheme that is not applicable to this standard is one in which the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission system that was intact except for the line that was out of service, as opposed to preventing a Cascading outage or Transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus, a standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems, and replace some other standards at the same time.

2.3.1 Frequently Asked Questions:

What exactly is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft standard.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant Facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-4 applies to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an under voltage load-shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation, as stated, indicates that the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission System that was intact, except for the line that was out of service, as opposed to preventing Cascading outage or Transmission System Collapse.
This standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary Load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a transmission Protection System bus differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

We have a UFLS scheme that, in some locales, sheds the necessary Load through non-BES circuit breakers and, occasionally, even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements, and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as, for example, a single failure to trip of a transmission Protection System bus differential lock-out relay.

How does the "Facilities" section of "Applicability" track with the standards that will be retired once PRC-005-2 becomes effective?

In establishing PRC-005-2, the drafting team combined legacy standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0. The merger of the subject matter of these standards is reflected in Applicability 4.2.

The intent of the drafting team is that the legacy standards be reflected in PRC-005-2 as follows:

- Applicability of PRC-005-1b for Protection Systems relating to non-generator elements of the BES is addressed in 4.2.1;
- Applicability of PRC-008-0 for underfrequency load shedding systems is addressed in 4.2.2;
- Applicability of PRC-011-0 for undervoltage load shedding relays is addressed in 4.2.3;
- Applicability of PRC-017-0 for Remedial Action Schemes is addressed in 4.2.4;
- Applicability of PRC-005-1b for Protection Systems for BES generators is addressed in 4.2.5 and 4.2.6.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE Device No. 86 (lockout relay) and IEEE Device No. 94 (tripping or trip-free relay), as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage-sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, seismic, thermal or gas accumulation) are not included.

Automatic Reclosing is addressed in PRC-005-3 by explicitly addressing them outside the definition of Protection System. The specific locations for applicable Automatic Reclosing are addressed in Applicability Section 4.2.~~6~~7.

Sudden Pressure Relaying is addressed in PRC-005-4 by explicitly addressing them outside the definition of Protection System. The specific locations for applicable Sudden Pressure Relaying are addressed in Applicability Section 4.2.1, 4.2.5.2~~,~~, 4.2.5.3, and 4.2.6. ~~and 4.2.5.4.~~

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

Yes. Automatic Reclosing includes reclosing relays and the associated dc control circuitry. Section 4.2.~~7~~6 of the Applicability specifically limits the applicable reclosing relays to:

4.2.~~7~~6 Automatic Reclosing

4.2.~~7~~6.1 Automatic Reclosing applied on the terminals of Elements connected to the BES bus located at generating plant substations where the total installed gross generating plant capacity is greater than the gross capacity of the largest BES generating unit within the Balancing Authority Area or, if a member of a Reserve Sharing Group, the largest generating unit within the Reserve Sharing Group.

4.2.~~7~~6.2 Automatic Reclosing applied on the terminals of all BES Elements at substations one bus away from generating plants specified in Section 4.2.~~7~~6.1

when the substation is less than 10 circuit-miles from the generating plant substation.

4.2.7~~6~~.3 Automatic Reclosing applied as an integral part of an RAS specified in Section 4.2.4.

Further, Footnote 1 to Applicability Section 4.2.7~~6~~ establishes that Automatic Reclosing addressed in 4.2.7~~6~~.1 and 4.2.7~~6~~.2 may be excluded if the equipment owner can demonstrate that a close-in three-phase fault present for twice the normal clearing time (capturing a minimum trip-close-trip time delay) does not result in a total loss of gross generation in the Interconnection exceeding the gross capacity of the largest relevant BES generating unit where the Automatic Reclosing is applied.

Additionally, Footnote 2 to Applicability Section 4.2.7~~6~~.1 advises that the entity's PSMP needs to remain current regarding the applicability of Automatic Reclosing Components relative to the largest generating unit within the Balancing Authority Area or Reserve Sharing Group.

The Applicability as detailed above was recommended by the NERC System Analysis and Modeling Subcommittee (SAMS) after a lengthy review of the use of reclosing within the BES. SAMS concluded that automatic reclosing is largely implemented throughout the BES as an operating convenience, and that automatic reclosing mal-performance affects BES reliability only when the reclosing is part of a Remedial Action Schemes, or when premature autoreclosing has the potential to cause generating unit or plant instability. A technical report, "Considerations for Maintenance and Testing of Autoreclosing Schemes — November 2012", is referenced in PRC-005-3 and provides a more detailed discussion of these concerns.

Why did the standard drafting team not include IEEE device numbers to describe Automatic Reclosing Relays?

The drafting team elected not to include IEEE device numbers to describe Automatic Reclosing because Automatic Reclosing component type could be a stand-alone electromechanical relay; or could be the 79 function within a microprocessor based multi-function relay(11).

What is synchronizing or synchronism ~~(Sync-Check - (25)) – check relay (Sync-Check - 25)~~?

A synchronizing device that produces an output that supervises ~~causes~~ closure of a circuit breaker between two circuits whose voltages are within prescribed limits of magnitude and~~, phase angle, and frequency~~. It may or may not include voltage or speed control. A sync-check relay permits the paralleling of two circuits that are within prescribed (usually wider) limits of voltage magnitude and~~, phase angle, and frequency~~.

~~*Is a sync-check (25) relay included in the Automatic Reclosing Control Circuitry?*~~

~~Where sync-check relays are included in an Automatic Reclosing scheme that is part of an RAS, the sync-check would be included in the control circuitry (Table 4-2(ab)).~~

~~Where sync-check relays are included in an Automatic Reclosing scheme that is not part of an RAS, the sync-check would not be included in the control circuitry (Table 4-2(a)).~~

~~The SDT asserts that a sync check (25) relay does not initiate closing but rather enables or disables closing and is not considered a part of the actual Automatic Reclosing control circuitry when not part of an RAS.~~

How do I interpret Applicability Section 4.2.7~~6~~ to determine applicability in the following examples:

At my generating plant substation, I have a total of 800 MW connected to one voltage level and 200 MW connected to another voltage level. How do I determine my gross capacity? Where do I consider Automatic Reclosing to be applicable?

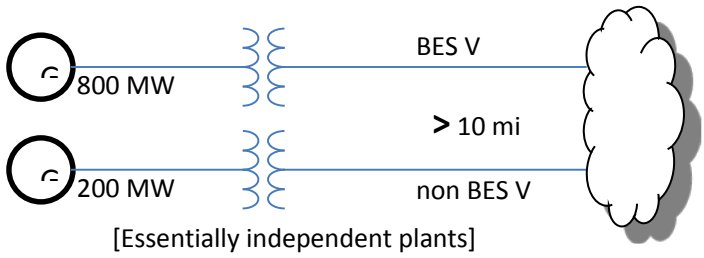
Scenario number 1:

The 800 MW of generation is connected to a BES voltage level bus, the 200 MW

is connected to a non-BES voltage level bus, and there is no connection between the two buses locally or within 10 circuit miles from the generating plant substation. The largest single unit in the BA area is 750 MW.

In this case, the total installed gross generating capacity would be 800 MW. The two units are essentially independent plants.

The BES voltage level bus is considered to be the bus to which the 800 MW of generation is connected. Any BES Automatic Reclosing at this location, as well as other locations within 10 circuit miles, is considered to be applicable because 800 MW exceeds the largest single unit in the BA area.



[Essentially independent plants]

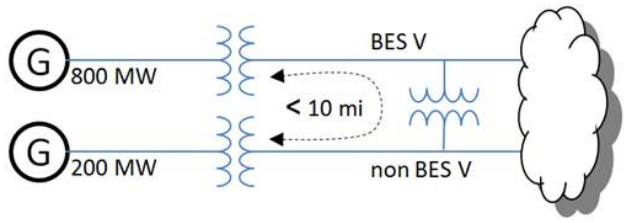
Gross Capacity	**Automatic Reclosing in scope**
800 MW	BES V

Scenario number 2:

The 800 MW of generation is connected to a BES voltage level bus, the 200 MW unit is connected to a non-BES voltage level bus, and there is a connection between the two buses locally or within 10 circuit miles from the generating plant substation. The largest single unit in the BA area is 750 MW.

In this case, reclosing into a fault on the BES system could impact the stability of the non-BES-connected generating units. Therefore, the total installed gross generating capacity would be 1000 MW.

The BES voltage level bus is considered to be the bus to which the 800 MW of generation is connected. Any BES Automatic Reclosing at this location, as well as other locations within 10 circuit miles, is considered to be applicable because total of 1000 MW exceeds the largest single unit in the BA area. However, the Automatic Reclosing on the non-BES voltage level bus is not applicable.



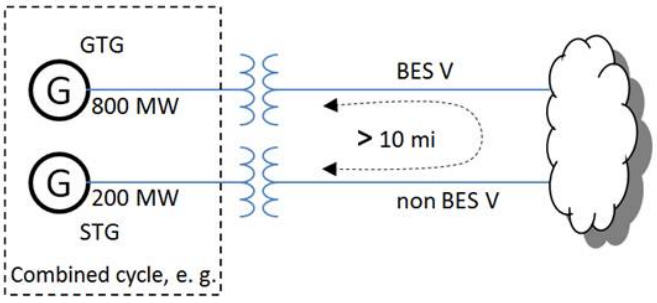
Gross Capacity	**Automatic Reclosing in scope**
1000 MW	BES V

Scenario number 3:

The 800 MW of generation is connected to a BES voltage level bus, the 200 MW unit is connected to a non-BES voltage level bus, and there is no connection between the two buses locally or within 10 circuit miles from the generating plant substation but the generating units connected at the BES voltage level do not operate independently of the units connected at the non BES voltage level (e.g., a combined cycle facility where 800 MW of combustion turbines are connected at a BES voltage level whose exhaust is used to power a 200 MW steam unit connected to a non BES voltage level. The largest single unit in the BA area is 750 MW.

In this case, the total installed gross generating capacity would be 1000 MW. Therefore, reclosing into a fault on the BES voltage level would result in a loss of the 800 MW combustion turbines and subsequently result in the loss of the 200 MW steam unit because of the loss of the heat source to its boiler.

The BES voltage level bus is considered to be the bus to which the 800 MW of generation is connected. Any BES Automatic Reclosing at this location, as well as other locations within 10 circuit miles, is considered to be applicable because total of 1000 MW exceeds the largest single unit in the BA area. However, the Automatic Reclosing on the non-BES voltage level bus is not applicable.



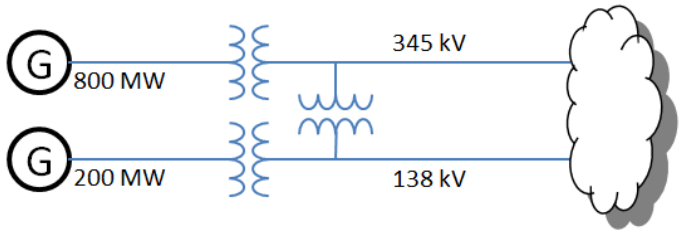
Gross Capacity	**Automatic Reclosing in scope**
1000 MW	BES V

Scenario 4

The 800 MW of generation is connected at 345 kV and the 200 MW is connected at 138 kV with an autotransformer at the generating plant substation connecting the two voltage levels. The largest single unit in the BA area is 900 MW.

In this case, the total installed gross generating capacity would be 1000 MW and section 4.2.7~~6~~.1 would be applicable to both the 345 kV Automatic Reclosing Components and the 138 kV Automatic Reclosing Components, since the total capacity of 1000 MW is larger than the largest single unit in the BA area.

However, if the 345 kV and the 138 kV systems can be shown to be uncoupled such that the 138 kV reclosing relays will not affect the stability of the 345 kV generating units then the 138 kV Automatic Reclosing Components need not be included per section 4.2.7~~6~~.1.



Gross Capacity	**Automatic Reclosing in scope**
1000 MW	BOTH*

* The study detailed in Footnote 1 of the draft standard may eliminate the 138 kV Automatic Reclosing Components and/or the 345 kV Automatic Reclosing Components

Why does 4.2.7~~6~~.2 specify "10 circuit miles"?

As noted in "Considerations for Maintenance and Testing of Autoreclosing Schemes — November 2012", transmission line impedance on the order of one mile away typically provides adequate impedance to prevent generating unit instability and a 10 mile threshold provides sufficient margin.

Should I use MVA or MW when determining the installed gross generating plant capacity?

Be consistent with the rating used by the Balancing Authority for the largest BES generating unit within their area.

What value should we use for generating plant capacity in 4.2.7~~6~~.1?

Use the value reported to the Balance Authority for generating plant capacity for planning and modeling purposes. This can be nameplate or other values based on generating plant limitations such as boiler or turbine ratings.

What is considered to be "one bus away" from the generation?

The BES voltage level bus is considered to be the generating plant substation bus to which the generator step-up transformer is connected. "One bus away" is the next bus, connected by either a transmission line or transformer.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.). Protective relays, providing only the functions mentioned in the question, are not included.

Are Reverse Power Relays installed on the low-voltage side of distribution banks considered to be components of "Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)"?

Reverse power relays are often installed to detect situations where the transmission source becomes de-energized and the distribution bank remains energized from a source on the low-voltage side of the transformer and the settings are calculated based on the charging current of the transformer from the low-voltage side. Although these relays may operate as a result of a fault on a BES element, they are not 'installed for the purpose of detecting' these faults.

Why is the maintenance of Sudden Pressure Relaying being addressed in PRC-005-4?

Proper performance of Sudden Pressure Relaying supports the reliability of the BES because fault pressure relays can detect rapid changes in gas pressure, oil pressure, or oil flow that are indicative of faults within liquid-filled, wire-wound equipment such as turn-to-turn faults which may be undetected by Protection Systems. Additionally, Sudden Pressure

Relaying can quickly detect faults and operate to limit damage to liquid-filled, wire-wound equipment.

What type of devices are classified as fault pressure relay?

There are three main types of fault pressure relays; rapid gas pressure rise, rapid oil pressure rise, and rapid oil flow devices.

Rapid gas pressure devices monitor the pressure in the space above the oil (or other liquid), and initiate tripping action for a rapid rise in gas pressure resulting from the rapid expansion of the liquid caused by a fault. The sensor is located in the gas space.

Rapid oil pressure devices monitor the pressure in the oil (or other liquid), and initiate tripping action for a rapid pressure rise caused by a fault. The sensor is located in the liquid.

Rapid oil flow devices ("Buchholz") monitor the liquid flow between a transformer/reactor and its conservator. Normal liquid flow occurs continuously with ambient temperature changes and with internal heating from loading and does not operate the rapid oil flow device. However, when an internal arc happens a sudden expansion of liquid can be monitored as rapid liquid flow from the transformer into the conservator resulting in actuation of the rapid oil flow device.

Are sudden pressure relays that only initiate an alarm included in the scope of PRC-005-4?

No, the definition of Sudden Pressure Relaying specifies only those that trip an interrupting device(s) to isolate the equipment it is monitoring.

Are pressure relief devices included in the scope of PRC-005-4?

No. PRDs are not included in the Sudden Pressure Relaying definition.

Is Sudden Pressure Relaying installed on distribution transformers included in PRC-005-4?

No, Applicability 4.2.1, ~~4.2.5.2, 4.2.5.3~~4.2.5, and 4.2.6~~, 4.2.5.4~~, explicitly describes what Sudden Pressure Relaying is included within the standard.

Are non-electrical sensing devices (other than fault pressure relays) such as low oil level or high winding temperatures included in PRC-005-4?

No, based on the SPCS technical document, "Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities – December 2013," the only applicable non-electrical sensing devices are Sudden Pressure Relays.

The standard specifically mentions auxiliary and lock-out relays. What is an auxiliary tripping relay?

An auxiliary relay, IEEE Device No. 94, is described in IEEE Standard C37.2-2008 as: "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device No. 86, is described in IEEE Standard C37.2 as: "A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely."

3. Protection System and Automatic Reclosing Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System and Automatic Reclosing both depend on the technological generation of the relays, as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices, such as primary measuring relays, monitoring devices, control Systems, and telecommunications equipment.

Modern microprocessor-based relays have six significant traits that impact a maintenance strategy:

- Self-monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs, such as trip coil continuity. Most relay users are aware that these relays have self-monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture Fault records showing how the Protection System responded to a Fault in its zone of protection, or to a nearby Fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-Fault times. The relays can compute values, such as MW and MVAR line flows, that are sometimes used for operational purposes, such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages, or from relay front panel button requests.
- Construction from electronic components, some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of battery chargers, associated communications equipment, voltage and current-measuring devices, and even the control circuitry (in the form of software-latches replacing lock-out relays, etc.).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

This standard also recognizes the distinct advantage of using advanced technology to justifiably defer or even eliminate traditional maintenance. Just as a hand-held calculator does not require routine testing and calibration, neither does a calculation buried in a microprocessor-based device that results in a "lock-out." Thus, the software-latch 86 that replaces an electro-mechanical 86 does not require routine trip testing. Any trip circuitry associated with the "soft 86" would still need applicable verification activities performed, but the actual "86" does not have to be "electrically operated" or even toggled.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System, Automatic Reclosing and Sudden Pressure Relaying Components are kept in working order and proper operation of malfunctioning Components is restored. A maintenance program for a specific Component includes one or more of the following activities:

- Verify — Determine that the Component is functioning correctly.
- Monitor — Observe the routine in-service operation of the Component.
- Test — Apply signals to a Component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — ~~Detect visible~~Examine for signs of Component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Automatic Reclosing – Includes the following Components:

- Reclosing relay
- Supervisory relay(s) – relay(s) that perform voltage and/or sync check functions that enables or disables operation of the reclosing relay
- Voltage sensing devices associated with the supervisory relay(s)
- Control circuitry associated with the reclosing relay or supervisory relay(s)~~.~~

Sudden Pressure Relaying – A system that trips an interrupting device(s) to isolate the equipment it is monitoring and includes the following Components:

- Fault pressure relay – a mechanical relay or device that detects rapid changes in gas pressure, oil pressure, or oil flow that are indicative of faults within liquid-filled, wire-wound equipment
- Control circuitry associated with a fault pressure relay

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual Components.

Component Type –

- Any one of the five specific elements of a Protection System.
- Any one of the ~~two~~ four specific elements of Automatic Reclosing.
- Any one of the two specific elements of Sudden Pressure Relaying.

Component – Any individual discrete piece of equipment included in a Protection System, Automatic Reclosing, or Sudden Pressure Relaying.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-32, and Table 5, which requires corrective action or a Protection System Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component, Automatic Reclosing or Sudden Pressure Relaying configuration or application errors are not included in Countable Events.

4.1 Frequently Asked Questions:

Why does PRC-005-4 not specifically require maintenance and testing procedures, as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-4 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the Tables 1-1 through 1-5, Table 2, Table 3, and Table 4 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program," PRC-005-4 establishes the activities and time basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by "restore" in the definition of maintenance.

The description of "restore" in the definition of a Protection System Maintenance Program addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R5 of the standard does require that the entity "shall demonstrate efforts to correct any identified Unresolved Maintenance Issues." Some examples of restoration (or correction of Unresolved Maintenance Issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to microprocessor-based relays following the discovery of failed components. Restoration, as used in this context, is not to be confused with restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices, and keeps them in working order. If an equipment item is repaired or replaced, then the entity can restart the maintenance-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades

might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

Please clarify what is meant by "...demonstrate efforts to correct an Unresolved Maintenance Issue..."; why not measure the completion of the corrective action?

Management of completion of the identified Unresolved Maintenance Issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requiring battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection System, Automatic Reclosing and Sudden Pressure Relaying Components are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System, and Sudden Pressure Relaying Components can have the ability to remotely conduct tests, either on-command or routinely; the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self-monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self-diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the standard itself, it is important to note that the concepts of CBM are a part of the standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the standard, the explanatory

discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

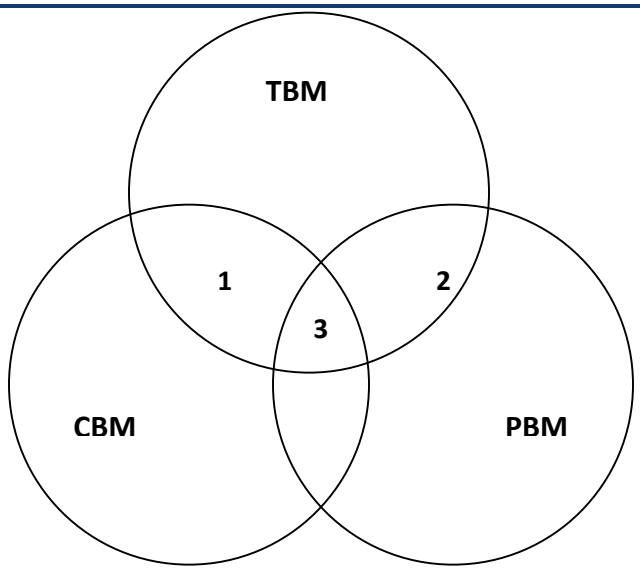
Microprocessor-based Protection System or Automatic Reclosing Components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours, or even milliseconds between non-disruptive self-monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram, the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



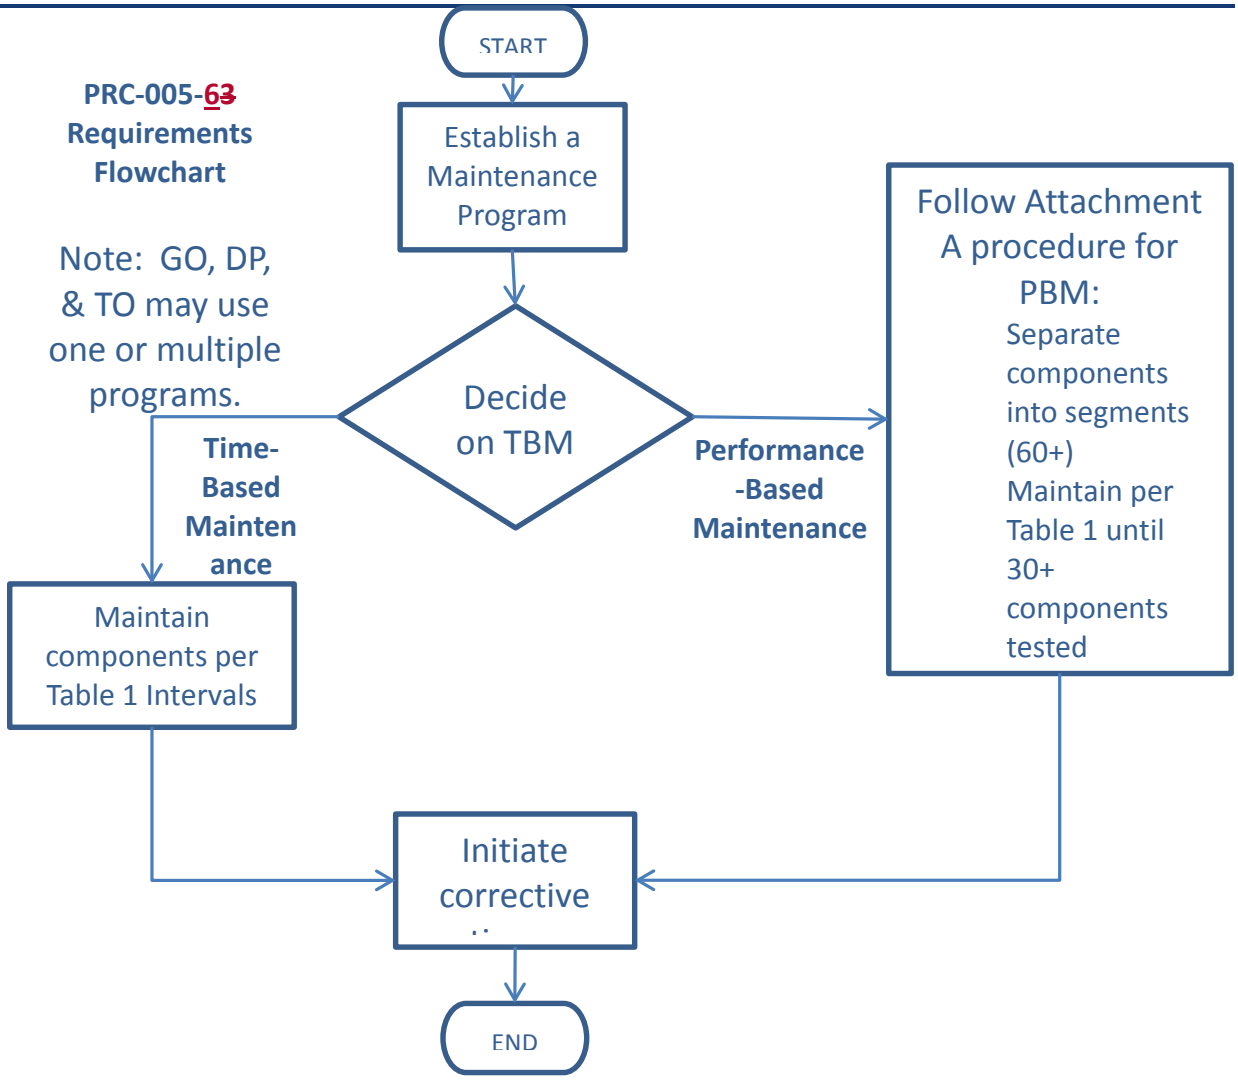
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2), in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals, then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a "flow chart" of the standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System Maintenance Program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self-monitoring device), then the intervals may be extended, or manual testing may be eliminated. This is referred to as condition-based maintenance or

CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended, while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance, or PBM. It is also sometimes referred to as reliability-centered maintenance, or RCM; but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a Fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Questions:

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) (in essence) state "…shall demonstrate efforts to correct ~~any~~ identified Unresolved Maintenance Issues." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System or Automatic Reclosing elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for Faults and Disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of Fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.

Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval. To use the extended time intervals available through Condition Based Maintenance, simply look for the rows in the Tables that refer to monitored items.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based (monitored) system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring, as per Requirement R1 (Part 1.2) of the standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device-level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements, as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure, but should be retrievable if requested by an auditor.

The applicability of R1.2 depends on the BES definition for Protection System to identify what components are to be covered by the Standard. One type of component is described as "Protective relays which respond to electrical quantities". Would a protection function that is embedded in a Generator's voltage regulator meet the BES defintion for Protection System and thus be included in R1.2?

Yes. The fact that these functions are implemented by an excitation system or voltage regulator rather than a classical looking relay is immaterial. The devices monitor electrical parameters such as voltage and/or current and cause a trip of the generator in response to these signals. By implementing these functions in the excitation system, the excitation system has in essence become an elaborate form of a microprocessor relay.

The voltage regulator processes electrical quantities and has an output that trips the generator breaker, quite often through a lockout. Examples include voltage regulator electronic cards that monitor voltage for high V/Hz, high exciter field voltage or both. In older generation regulators (1980s and 1990s) the protection functions are essentially electronic relays (not

electromechanical or microprocessor based but using transistors and potentiometers). Should either excess voltage condition be true, a contact mounted on the voltage regulator electronics board closes which, in turn, goes to an auxiliary relay or activates a lockout relay directly. The electronic quantities monitored include exciter field voltage, generator current, and generator terminal voltage.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based (or monitored) maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule, dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1b that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-4. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System or Automatic Reclosing owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection System and Automatic Reclosing Components to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in the Tables of PRC-005-4.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a "One Calendar Year Interval," the next event would have to occur on or before December 31, 2010.

Please provide an example of "4 Calendar Months".

If a maintenance activity is described as being needed every four Calendar Months then it is performed in a (given) month and due again four months later. For example a battery bank is inspected in month number 1 then it is due again before the end of the month number5. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of May. Another example could be that a four-month inspection was performed in January is due in May, but if performed in March (instead of May) would still

be due four months later therefore the activity is due again July. Basically every "four Calendar Months" means to add four months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but is not limited to, an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self-diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2, the particular components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance

- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests or other measurements indicative of battery performance are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power System input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored Control Circuitry Associated with Protective Functions" section'
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented lead-acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank trending of ohmic values or other measurements indicative of battery performance to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip
- Battery performance test (if internal ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- All trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions" section
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #3: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self-diagnosis and alarms. (monitored)

- Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
- Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular components shall have maximum activity intervals of:

Every four calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank trending of ohmic values or other measurements indicative of battery performance to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Condition of all individual battery cells (where visible)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests or other measurements indicative of battery performance are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions section
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example, a battery will always need some kind of inspection.

We have a 30-year-old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years, or when an Unresolved Maintenance Issue arises. The control circuitry can be maintained every 12 years. The circuit breaker trip coil(s) has to be electrically operated at least once every six years.

What is a mitigating device?

A mitigating device is the device that acts to respond as directed by a Remedial Action Schemes. It may be a breaker, valve, distributed control system, or any variety of other devices. This response may include tripping, closing, or other control actions.

8. Maximum Allowable Verification Intervals

The maximum allowable testing intervals and maintenance activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection System or Automatic Reclosing requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no Fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying Fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), Table 2, Table 3, Table 4-1 through Table 4-3~~2~~, and Table 5 in the standard specify maximum allowable verification intervals for various generations of Protection Systems, Automatic Reclosing and Sudden Pressure Relaying and categories of equipment that comprise these systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted transmission Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a generation Protection System. The various sub-systems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and RAS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and RAS all use identical equipment as Protection Systems in the performance of their functions; and, therefore, have the same maintenance needs.

Distributed UFLS and UVLS Systems, which use local sensing on the distribution System and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-4:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits.
    - Table 2, is for alarms; this was broken out to simplify the other tables.
    - Table 3 is for components which make-up distributed UFLS and UVLS Systems.
    - Table 4 is for Automatic Reclosing.
    - Table 5 is for Sudden Pressure Relaying.
- Next look within that table for your device and its degree of monitoring. The Tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your Performance-Based Maintenance (PBM) plan requires more activities, then you must perform and document to this higher standard. (Note that this does not apply unless you utilize PBM.)
- After the maintenance activity is known, check the maximum maintenance interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your Performance-Based Maintenance plan requires activities more often than the Tables maximum, then you must perform and document those activities to your more stringent standard. (Note that this does not apply unless you utilize PBM.)
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every four months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available in each of the Tables. While the maintenance activities resulting from this choice would require more maintenance man-

hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System Component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. For each Automatic Reclosing Component, Table 4 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-4. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-4, most notable of which is an entity using performance based maintenance methodology.

If an entity has a Performance-Based Maintenance program, then that plan must be followed, even if the plan proves to be more stringent than the minimums laid out in the Tables.

If an entity has a Time-Based Maintenance program and the PSMP is more stringent than PRC-005-4, they will only be audited in accordance with the standard (minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3~~2~~, and Table 5).

8.1.2 Additional Notes for Tables 1-1 through 1-5, Table 3, and Table 4

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc., are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or RAS (as opposed to a monitoring task) must be verified as a component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components, physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might want to follow the guidelines in the applicable IEEE recommended practices for battery maintenance and testing, especially if the battery in question is used for application requirements in addition to the protection and control demands covered under this

standard. However, the Standard Drafting Team has tailored the battery maintenance and testing guidelines in PRC-005-4 for the Protection System owner which are application specific for the BES Facilities. While the IEEE recommendations are all encompassing, PRC-005-4 is a more economical approach while addressing the reliability requirements of the BES.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus, these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & current sensing device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected (phase value and phase relationships are both equally important to verify).

7. "End-to-end test," as used in this Supplementary Reference, is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test, it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc control circuitry. A documented Real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc control circuit trip. Or another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a Real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities, but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the standard is technology- and method-neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor- based relays. For relay maintenance departments that choose to test microprocessor-based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously

disabled, but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the standard states "…settings are as specified."

Many of the microprocessor- based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement, a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection; and, thus, the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable, as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system Disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known Fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked.

Do I have to perform a full end-to-end test of a Remedial Action Schemes?

No. All portions of the -RAS need to be maintained, and the portions must overlap, but the overall RAS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about RAS interfaces between different entities or owners?

As in all of the Protection System requirements, RAS segments can be tested individually, thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Remedial Action Schemes?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Remedial Action Schemes (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Remedial Action Schemes or relay sensing for non-distributed UFLS or UVLS Systems?

Since components of the RAS, UFLS and UVLS are the same types of components as those in Protection Systems, then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for RAS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example, an RAS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the Real-time tripping of an RAS scheme should that occur. Forced trip tests of circuit breakers (etc.) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance, as required, due to a major natural disaster (hurricane, earthquake, etc.), how will this affect my compliance with this standard?

The Sanction Guidelines of the North American Electric Reliability Corporation, effective January 15, 2008, provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays; or, even worse, I am experiencing numerous relay Misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But any entity can choose to test some or all of their Protection System components more frequently (or to express it differently, exceed the minimum requirements of the standard). Particularly if you find that the maximum intervals in the standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest.

We believe that the four-month interval between inspections is unneccessary. Why can we not perform these inspections twice per year?

The Standard Drafting Team, through the comment process, has discovered that routine monthly inspections are not the norm. To align routine station inspections with other important inspections, the four-month interval was chosen. In lieu of station visits, many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years. If we are unable to achieve this schedule, but we are able to complete the procedures in less than the maximum time interval ,then are we in or out of compliance?

According to R3, if you have a time-based maintenance program, then you will be in violation of the standard only if you exceed the maximum maintenance intervals prescribed in the Tables. According to R4, if your device in question is part of a Performance-Based Maintenance program, then you will be in violation of the standard if you fail to meet your PSMP, even if you do not exceed the maximum maintenance intervals prescribed in the Tables. The intervals in the Tables are associated with TBM and CBM; Attachment A is associated with PBM.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, generator connected station service or generator connected excitation transformer to meet the requirements of this maintenance standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay, may include, but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays

- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step-up, generator-connected station service transformers, or generator connected excitation transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit; and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary Loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program, even if the loss of the those Loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program, even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the Protection Systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating Facility?

The SDT does not intend that the system-connected station service transformers be included in the Applicability. The generator-connected station service transformers and generator connected excitation transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping," one needs to realize that sometimes there are more inputs and outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output

terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every six years, unless PBM methodology is applied.

The contacts on the 86 or auxiliary tripping relays (94) that change state to pass on the trip current to a breaker trip coil need only be checked every 12 years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent Load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and Load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an RAS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three-year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-4 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component Type.

For Requirement R2, Requirement R3, and Requirement R4, in cases where the interval of the maintenance activity is longer than the audit cycle, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performance of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component. In cases where the interval of the maintenance activity is shorter than the audit cycle, documentation of all performances (in accordance with the tables) of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component since the previous scheduled audit date shall be retained.

For Requirement R5 the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of Unresolved Maintenance Issues identified by the entity since the last audit, including all that were resolved since the last audit.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

The SDT is aware that, in some cases, the retention period could be relatively long. But, the retention of documents simply helps to demonstrate compliance.

8.2.1 Frequently Asked Questions:

Please clarify the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld.

Maximum Maintenance Interval	**Data Retention Period**
4 Months, 6 Months,18 Months, or 3 Years	All activities since previous audit
6 Years	All activities since previous audit(assuming a 6 year audit cycle) or most recent performance(assuming 3 year audit cycle), whichever is longer
12 Year	All activities from the most recent performance

If an entity prefers to utilize Performance-Based Maintenance, then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced, then the entity can restart the maintenance-time-interval-clock if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a Facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the

maintenance activities specified in the Tables of PRC-005-4, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-Fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation, and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-4 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-4 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components, such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content; and, therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-4 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing, as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates, then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized, there are cases when degradation can take place, even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2% or 8% when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its 100 Protection System components, which would equate to 2% for application to the VSL Table for Requirement R3. This VSL is written to compare missed components to total components. In this case two components out of 100 were missed, or 2%.

How do I achieve a "grace period" without being out of compliance?

The objective here is to create a time extension within your own PSMP that still does not violate the maximum time intervals stated in the standard. Remember that the maximum time intervals listed in the Tables cannot be extended.

For the purposes of this example, concentrating on just unmonitored protective relays – Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of six calendar years. Your plan must ensure that your unmonitored relays are tested at least once every six calendar years. You could, within your PSMP, require that your unmonitored relays be tested every four calendar years, with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders, but still has the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, in effect a grace period within your PSMP, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of four years; it also has a built-in time extension allowed within the PSMP, and yet does not exceed the maximum time interval allowed by the standard. So while there are no time extensions allowed beyond the standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007, the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak Load, or 4% of the NERC peak Load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak Load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of five years for electromechanical or solid state relays, and seven years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond seven years, based on favorable experience with the particular products they have installed. To

provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1], as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1, only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay, as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system Element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a Fault occurs, leading to failure to operate for the Fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self-test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal Fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup Fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for relay unavailability and abnormal unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years –

the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay mean time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for "time-interval extensions" or "grace periods" to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally, it was again noted that FERC Order 693 demanded maximum time intervals. "Maximum time intervals" by their very term negates any "time-interval extension" or "grace periods." To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension, while still following FERC Order 693, the Standard Drafting Team arrived at a six-year interval for the electromechanical relay, instead of the five-year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10-year interval was chosen, even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus, the maximum allowed interval for these components has been set to 12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval." The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year number one need not be revisited until six years later (year number seven). For example, a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP, the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals, other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major System outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality Management Systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program, the asset owner must first sort the various Components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM, but does not own 60 units to comprise a population, then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment, and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries, but can be applied to all other Components, including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003.)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005.)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968.)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason, the following assumptions are made:

B = 5%

z = 1.96 (This equates to a 95% confidence level)

π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%

z = 1.44 (85% confidence level)

π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined, then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% Countable Events. It is notable that 4% is specifically chosen because an entity with a small population (30 units) would have to adjust its time intervals between maintenance if more than one Countable Event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of Countable Events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more), then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the Countable Events is less than 4%; this must be attained within three years.

Performance-Based Program Evaluation Example

The 4% performance target was derived as a protection system performance target and was selected based on the drafting team's experience and studies performed by several utilities. This is not derived from the performance of discrete devices. Microprocessor relays and electromechanical relays have different performance levels. It is not appropriate to compare these performance levels to each other. The performance of the segment should be compared to the 4% performance criteria.

In consideration of the use of Performance Based Maintenance (PBM), the user should consider the effects of extended testing intervals and the established 4% failure rate. In the table shown below, the segment is 1000 units. As the testing interval (in years) increases, the number of units tested each year decreases. The number of countable events allowed is 4% of the tested units. Countable events are the failure of a Component requiring repair or replacement, any corrective actions performed during the maintenance test on the units within the testing segment (units per year), or any misoperation attributable to hardware failure or calibration failure found within the entire segment (1000 units) during the testing year.

Example: 1000 units in the segment with a testing interval of 8 years: The number of units tested each year will be 125 units. The total allowable countable events equals: 125 X .04 = 5. This number includes failure of a Component requiring repair or replacement, corrective issues found during testing, and the total number of misoperations (attributable to hardware or calibration failure within the testing year) associated with the entire segment of 1000 units.

Example: 1000 units in the segment with a testing interval of 16 years: The number of units tested each year will be 63 units. The total allowable countable events equals: 63 X .04 = 2.5.

As shown in the above examples, doubling the testing interval reduces the number of allowable events by half.

Total number of units in the segment	1000
Failure rate	4.00%

Testing Intervals (Years)	Units Per Year	Acceptable Number of Countable Events per year	Yearly Failure Rate Based on 1000 Units in Segment
1	1000.00	40.00	4.00%
2	500.00	20.00	2.00%
4	250.00	10.00	1.00%
6	166.67	6.67	0.67%
8	125.00	5.00	0.50%
10	100.00	4.00	0.40%
12	83.33	3.33	0.33%
14	71.43	2.86	0.29%
16	62.50	2.50	0.25%
18	55.56	2.22	0.22%
20	50.00	2.00	0.20%

Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

Segment – Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual Components.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5, Table 3, Table 4-1 through Table 4-3~~2~~, and Table 5, which requires corrective action or a Protection System Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component, Automatic Reclosing, or Sudden Pressure Relaying configuration or application errors are not included in Countable Events.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance

intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No, you must use actual in-service test data for the components in the segment.

What types of Misoperations or events are not considered Countable Events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable Events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System Misoperations during system installation or maintenance activities are not considered Countable Events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES Element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused Misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure

rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause Misoperations are not considered Countable Events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a Unresolved Maintenance Issue as a result of a Misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required Misoperation investigation/corrective action), the actions performed can count as a maintenance activity provided the activities in the relevant Tables have been done, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the Unresolved Maintenance Issue as a Countable Event within the relevant component group segment and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of four relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a Misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually

could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of four years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system Disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of

monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60. They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate. This entity is now allowed to extend the maintenance interval if they choose. The entity chooses to extend the maintenance interval of this population segment out to 10 years. This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year. After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures. This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year). In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year, they again find six failures out of the 125 units tested. 6/125= 5% failures. In response to the 5% failure rate, the entity decreases the testing interval to seven years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected. After a year, they again find six failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried five years and they were under the 4% limit and they tried seven years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to five years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to six years. This means that they will now test 167 units per year (1000/6). After a year, they again find six failures out of the 167 units tested. 6/167= 3.6% failures. Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at six years or less. Entity chose six-year interval and effectively extended their TBM (five years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element.

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment –*Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 1,000 circuit breakers, all of which have two trip coils, for a total of 2,000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard, then this is greater than the minimum sample requirement of 60.

For the sake of further example, the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring, and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago, the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their control circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the

operations control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2,000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored; therefore, the trip paths are continuously tested and the circuit will alarm when there is a failure. These alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification, and is taking care of this activity through other documentation of Real-time Fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12-year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the 4% limit; and they tried 14 years, and they were over the 4% limit. They must be back at 4% failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval, and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific Element. This entity calls this set of protective relays a "Relay Scheme." Thus, this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages, whereas a transmission maintenance group might create a process that utilizes Real-time system values measured at the relays.

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment –*Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes," all of which have three current signals supplied from bushing CTs, and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard, and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1,000) are supplied with current signals from ANSI STD C800 bushing CTs and voltage signals from PTs built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards, and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs), as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent

(standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2,000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored; therefore, the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).

(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay, all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PTs). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level; thus, any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4%failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the 4% limit; and they tried 14 years, and they were over the 4% limit. They must be back at 4% failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1,000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chose
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment, as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above, or Attachment A of the standard;
- Opportunistic verification using analysis of Fault records, as described in Section 11

10.1 Frequently Asked Questions:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the Unresolved Maintenance Issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve Fault event records and oscillographic records by data communications after a Fault. They analyze the data closely if there has been an apparent Misoperation, as NERC standards require. Some advanced users have commissioned automatic Fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured Digital Fault Recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of Faults in the vicinity of the relay that produce relay response records and the specific data captured.

A typical Fault record will verify particular parts of certain Protection Systems in the vicinity of the Fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external Fault records that completely verify the Protection System.

For example, Fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that Fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a Fault just outside their respective zones of protection. The ensemble of internal Fault and nearby external Fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using Fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple Faults close to either side of a setting boundary, setting or calibration could still be incorrect.

PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If Fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the Fault records used, and the maintenance-related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Questions:

I use my protective relays for Fault and Disturbance recording, collecting oscillographic records and event records via communications for Fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as Disturbance Monitoring Equipment, NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements and is being addressed by a standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of Fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them; for background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple: With legacy relays (non-microprocessor protective relays), it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays, it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process, there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade, then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle.

(However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays, then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced, then the entity can restart the maintenance-activity-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan, and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment, then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards, then the requirements of PRC-005-4 are simple – if the Protection System component performs a Protection System function, then it must be maintained. If the component no longer performs Protection System functions, then it does not require maintenance activities under the Tables of PRC-005-4. While many entities might physically remove a component that is no longer needed, there is no requirement in PRC-005-4 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-4 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System, it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement, even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-4 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-4 requirement, although the protective device may be unable to be returned to service under normal calibration adjustments. R5 states:

"R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct any identified Unresolved Maintenance Issues."

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC standards.

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) state "…shall demonstrate efforts to correct any identified Unresolved Maintenance Issues..." The type of corrective activity is not stated; however, it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity might ask about the status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring, the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Tables 1, 3, 4 and 5 and any associated sub-tables~~Table 3~~.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

This manufacturer's information can be used by the registered entity to document compliance of the monitoring attributes requirements by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission Facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to an Unresolved Maintenance Issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Tables 1, 3, 4 and 5 and any associated sub-tables~~Table 3~~.

13.1 Frequently Asked Questions:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring, the standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System or Automatic Reclosing Failures

When a failure occurs in a Protection System or Automatic Reclosing, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable Loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System or Automatic Reclosing owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance, but if its battery maintenance program is lacking, then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-4 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore, *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a Faulted Element of the BES. Devices that sense thermal, vibration, seismic, gas, or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor-based equipment in the following ways; the relays should meet the asset owners' tolerances:

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.1.1 Frequently Asked Questions:

What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device, all the way to the protective relay. The following observations apply:

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; including, but not limited to, the following: By calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this, therefore, tests the CT, as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during Load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the Real-time Loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay, then the verification activity has been satisfied. Thus, event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and VArs around the entire bus; this should add up to zero watts and zero VArs, thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current-sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample.

15.2.1 Frequently Asked Questions:

What is meant by "… verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current-sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds.
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay) to another protective relay monitoring the same line, with currents supplied by different CTs.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc.) and verified by calculations and known ratios to be the values expected. For example, a single PT on a 100KV bus will have a specific secondary value that, when multiplied by the PT ratio, arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring Systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being

shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions, as do microprocessor- based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment, like voltmeters and clamp on ammeters, to measure the input signals to the relays. This practice seems very risky, and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays, but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests, such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path, then the manual-intervention testing of those parallel trip paths can be eliminated; however, the actual operation of the circuit breaker must still occur at least once every six years. This six-year tripping requirement can be completed as easily as tracking the Real-time Fault-clearing operations on the circuit breaker, or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment, and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device, if this ground switch is utilized in a Protection System and forces a ground Fault to occur that then results in an expected Protection System operation to clear the forced ground Fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years, and any electromechanically operated device will have to be tested every six years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit, then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If the lock-out relays (86) are electromechanical type components, then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such, there is a six-year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 and/or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Contacts of the 86 and/or 94 lock relay that operate non-BES interrupting devices are not required. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment. The requirement for these systems is verification of the tripping path.

Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual component's maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-4 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-4 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as Fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-4 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5? (Refer to Table 3 for examples 1 and 2) Example 1: A non-BES circuit breaker that is tripped via a Protection System to which PRC-005-4 applies might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial Loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

Example 2: A Transmission Owner may have a non-BES breaker that is tripped via a Protection System to which PRC-005-4 applies, which may be (but is not limited to) a 13.8 KV circuit breaker feeding (non-black-start) radial Loads but has a trip that originates from a BES 115KV line relay.

- The relay must be verified
- The voltage signal to the relay must be verified
- All of the relevant dc supply tests still apply

- The unmonitored trip circuit between the relay and any lock-out (86) or auxiliary (94) relay must be verified every 12 years
- The unmonitored trip circuit between the lock-out (86) (or auxiliary (94)) relay and the non-BES breaker does not have to be proven with an electrical trip
- In the case where there is no lockout (86) or auxiliary (94) tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip

Example 3: A Generator Owner may have a non-BES circuit breaker that is tripped via a Protection System to which PRC-005-4 applies, such as the generator field breaker and low-side breakers on station service/excitation transformers connected to the generator bus.

Trip testing of the generator field breaker and low side station service/excitation transformer breaker(s) via lockout or auxiliary tripping relays are not required since these breakers may be associated with radially fed loads and are not considered to be BES breakers. An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 6.9kV station service transformer source circuit breaker but has a trip that originates from a generator differential (87) relay.

- The differential relay must be verified.
- The current signals to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

However, it is very prudent to verify the tripping of such breakers for the integrity of the overall generation plant.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?

Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

The NERC definition of a Protection System is:

- Protective relays which respond to electrical quantities,

- Communications Systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System, "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery Systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply, as mentioned in the definition of Protective System?

The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers, as well as dc systems that do not utilize batteries. This revision of PRC-005-4 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies besides the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new, the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity (no open circuits) of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity – lack of an open circuit. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal (no open circuit). Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. Whether it is caused from an open cell or a bad external connection, an open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path, the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor-based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- Loss of electrical continuity of the station battery will cause, in most battery chargers, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional one- to two-second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed, which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery, unless the battery charger is taken out of service. At that time,

a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the standard prescribes what must be accomplished during the maintenance activity, it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged, there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.
- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- Manufacturers of microprocessor-controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.
- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.
- Internal ohmic measurements of the cells and units of lead-acid batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string; and when used in conjunction with resistance measurements of the battery's external connections, can prove continuity. Also some methods of taking internal ohmic measurements, by their very nature, can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.
- Specific gravity tests could infer continuity because without continuity there could be no charging occurring; and if there is no charging, then specific gravity will go down below acceptable levels over time.

No matter how the electrical continuity of a battery set is verified, it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as manufactured?

The answer to this question depends on the type of battery (valve-regulated lead-acid, vented lead-acid, or nickel-cadmium) and the maintenance activity chosen.

For example, if you have a valve-regulated lead-acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than

every six months. While this interval might seem to be quite short, keep in mind that the six-month interval is important for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is incapable of performing as manufactured.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every three calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead-acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station battery's ability to perform as manufactured, they should be made at some point in time after the installation to allow the cell chemistry to stabilize after the initial freshening charge. An accepted industry practice for establishing baseline values is after six-months of installation, with the battery fully charged and in service. However, it is recommended that each owner, when establishing a baseline, should consult the battery manufacturer for specific instructions on establishing an ohmic baseline for their product, if available.

When internal ohmic measurements are taken, the same make/model test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Conductance" test equipment, even though both manufacturers have produced "Ohmic" test equipment. Therefore, for meaningful results to an established baseline, the same make/model of instrument should be used.

For all new installations of valve-regulated lead-acid (VRLA) batteries and vented lead-acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as manufactured, the establishment of the baseline, as described above, should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries, the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also, several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However, it is important that when using battery manufacturer-supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment). Although many manufacturers may have provided baseline values, which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for

the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For vented lead-acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges, the active electrolyte, sulfuric acid, is consumed and the concentration of the sulfuric acid in water is reduced. This, in turn, reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can, therefore, be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely, if taken shortly after adding water to the cell, the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and valve-regulated lead-acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries, and for VLA batteries also, where another method besides taking hydrometer readings is desired, the state of charge may be determined by taking voltage and current readings at the battery terminals. The methods employed to obtain accurate readings vary for the different battery types. Manufacturers' information and IEEE guidelines can be consulted for specifics; (see IEEE 1106 Annex B for Nickel Cadmium batteries, IEEE 1188 Annex A for VRLA batteries and IEEE 450 for VLA batteries.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery, a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external

circuit terminations. Your method of checking for acceptable values of intercell and terminal connection resistance could be by individual readings, or a combination of the two. There are test methods presently that can read post termination resistances and resistance values between external posts. There are also test methods presently available that take a combination reading of the post termination connection resistance plus the intercell resistance value plus the post termination connection resistance value. Either of the two methods, or any other method, that can show if the adequacy of connections at the battery posts is acceptable.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen, not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal colors (which are an indicator of sulfation or possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections, such as the bus bar connection to each plate, and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell, or cells, must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery, nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why is it necessary to verify the battery string can perform as manufactured? I only care that the battery can trip the breaker, which means that the battery can perform as designed. I oversize my batteries so that even if the battery cannot perform as manufactured, it can still trip my breakers.

The fundamental answer to this question revolves around the concept of battery performance "as designed" vs. battery performance "as manufactured." The purpose of the various sections of Table 1-4 of this standard is to establish requirements for the Protection System owner to maintain the batteries, to ensure they will operate the equipment when there is an incident that requires dc power, and ensure the batteries will continue to provide adequate service until at least the next maintenance interval. To meet these goals, the correct battery has to be properly selected to meet the design parameters, and the battery has to deliver the power it was manufactured to provide.

When testing batteries, it may be difficult to determine the original design (i.e., load profile) of the dc system. This standard is not intended as a design document, and requirements relating to design are, therefore, not included.

Where the dc load profile is known, the best way to determine if the system will operate as designed is to conduct a service test on the battery. However, a service test alone might not fully determine if the battery is healthy. A battery with 50% capacity may be able to pass a service test, but the battery would be in a serious state of deterioration and could fail at some point in the near future.

To ensure that the battery will meet the required load profile and continue to meet the load profile until the next maintenance interval, the installed battery must be sized correctly (i.e., a correct design), and it must be in a good state of health. Since the design of the dc system is not within the scope of the standard, the only consistent and reliable method to ensure that the battery is in a good state of health is to confirm that it can perform as manufactured. If the battery can perform as manufactured and it has been designed properly, the system should operate properly until the next maintenance interval.

How do I verify the battery string can perform as manufactured?

Optimally, actual battery performance should be verified against the manufacturer's rating curves. The best practice for evaluating battery performance is via a performance test. However, due to both logistical and system reliability concerns, some Protection System owners prefer other methods to determine if a battery can perform as manufactured. There are several battery parameters that can be evaluated to determine if a battery can perform as manufactured. Ohmic measurements and float current are two examples of parameters that have been reported to assist in determining if a battery string can perform as manufactured.

The evaluation of battery parameters in determining battery health is a complex issue, and is not an exact science. This standard gives the user an opportunity to utilize other measured parameters to determine if the battery can perform as manufactured. It is the responsibility of the Protection System owner, however, to maintain a documented process that demonstrates the chosen parameter(s) and associated methodology used to determine if the battery string can perform as manufactured.

Whatever parameters are used to evaluate the battery (ohmic measurements, float current, float voltages, temperature, specific gravity, performance test, or combination thereof), the goal is to determine the value of the measurement (or the percentage change) at which the battery fails to perform as manufactured, or the point where the battery is deteriorating so rapidly that it will not perform as manufactured before the next maintenance interval.

This necessitates the need for establishing and documenting a baseline. A baseline may be required of every individual cell, a particular battery installation, or a specific make, model, or size of a cell. Given a consistent cell manufacturing process, it may be possible to establish a baseline number for the cell (make/model/type) and, therefore, a subsequent baseline for every installation would not be necessary. However, future installations of the same battery types should be spot-checked to ensure that your baseline remains applicable.

Consistent testing methods by trained personnel are essential. Moreover, it is essential that these technicians utilize the same make/model of ohmic test equipment each time readings are taken in order to establish a meaningful and accurate trend line against the established baseline. The type of probe and its location (post, connector, etc.) for the reading need to be the same for each subsequent test. The room temperature should be recorded with the readings for each test as well. Care should be taken to consider any factors that might lead a trending program to become invalid.

Float current along with other measureable parameters can be used in lieu of or in concert with ohmic measurement testing to measure the ability of a battery to perform as manufactured. The key to using any of these measurement parameters is to establish a baseline and the point where the reading indicates that the battery will not perform as manufactured.

The establishment of a baseline may be different for various types of cells and for different types of installations. In some cases, it may be possible to obtain a baseline number from the battery manufacturer, although it is much more likely that the baseline will have to be established after the installation is complete. To some degree, the battery may still be "forming" after installation; consequently, determining a stable baseline may not be possible until several months after the battery has been in service.

The most important part of this process is to determine the point where the ohmic reading (or other measured parameter(s)) indicates that the battery cannot perform as manufactured. That point could be an absolute number, an absolute change, or a percentage change of an established baseline.

Since there are no universally-accepted repositories of this information, the Protection System owner will have to determine the value/percentage where the battery cannot perform as manufactured (heretofore referred to as a failed cell). This is the most difficult and important part of the entire process.

To determine the point where the battery fails to perform as manufactured, it is helpful to have a history of a battery type, if the data includes the parameter(s) used to evaluate the battery's ability to perform as manufactured against the actual demonstrated performance/capacity of a battery/cell.

For example, when an ohmic reading has been recorded that the user suspects is indicating a failed cell, a performance test of that cell (or string) should be conducted in order to prove/quantify that the cell has failed. Through this process, the user needs to determine the ohmic value at which the performance of the cell has dropped below 80% of the manufactured, rated performance. It is likely that there may be a variation in ohmic readings that indicates a failed cell (possibly significant). It is prudent to use the most conservative values to determine the point at which the cell should be marked for replacement. Periodically, the user should

demonstrate that an “adequate” ohmic reading equates to an adequate battery performance (>80% of capacity).

Similarly, acceptance criteria for "good" and "failed" cells should be established for other parameters such as float current, specific gravity, etc., if used to determine the ability of a battery to function as designed.

What happens if I change the make/model of ohmic test equipment after the battery has been installed for a period of time?

If a user decides to switch testers, either voluntarily or because the equipment is not supported/sold any longer, the user may have to establish a new base line and new parameters that indicate when the battery no longer performs as manufactured. The user always has a choice to perform a capacity test in lieu of establishing new parameters.

What are some of the differences between lead-acid and nickel-cadmium batteries?

There is a marked difference in the aging process of lead acid and nickel-cadmium station batteries. The difference in the aging process of these two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. In contrast, the primary failure of nickel-cadmium batteries is due to the gradual linear aging of the active materials in the plates. The electrolyte of a nickel-cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued corrosion of the positive plate and grid structure throughout its operational life while a nickel-cadmium battery does not.

Changes to the properties of a lead acid battery when periodically measured and trended to a baseline, can indicate aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate.

Because of the clear differences in the aging process of lead acid and nickel-cadmium batteries, there are no significantly measurable properties of the nickel-cadmium battery that can be measured at a periodic interval and trended to determine aging. For this reason, Table 1-4(c) (Protection System Station dc supply Using nickel-cadmium [NiCad] Batteries) only specifies one minimum maintenance activity and associated maximum maintenance interval necessary to verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance against the station battery baseline. This maintenance activity is to conduct a performance or modified performance capacity test of the entire battery bank.

Why in Table 1-4 of PRC-005-4 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.
Because the battery rack is specifically manufactured for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the “Unintentional dc Grounds” requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional ~~DC~~ dc ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional ~~DC~~ dc grounds. The standard merely requires that a check be made for the existence of u~~U~~nintentional dc~~DC~~ g~~G~~rounds. Obviously, a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for u~~U~~nintentional ~~DC~~ dc g~~G~~rounds because of the possible consequences to the Protection System.

Where the standard refers to "all cells," is it sufficient to have a documentation method that refers to "all cells," or do we need to have separate documentation for every cell? For example, do I need 60 individual documented check-offs for good electrolyte level, or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this standard refer to Station batteries or all batteries; for example, Communications Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to communications sites. The batteries covered under PRC-005-4 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point, the corrective actions can be initiated.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry, these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example, in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac

current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand, dc resistance of a cell is measured by a third manufacturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices, there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to always get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit internal ohmic measurements (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a baseline and trending it over time says, "…depending on the degree of change a performance test, cell replacement or other corrective action may be necessary…" (IEEE std 1188-2005, C.4 page 18).

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century, EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity, but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity," they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as manufactured. By evaluation of the trending

of the ohmic measurements over time, the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this condition based approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as manufactured.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4. In cases where individual cells in a multi-cell unit are inaccessible, an ohmic measurement of the entire unit may be made.

I have a concern about my batteries being used to support additional auxiliary loads beyond my protection control systems in a generation station. Is ohmic measurement testing sufficient for my needs?

While this standard is focused on addressing requirements for Protection Systems, if batteries are used to service other load requirements beyond that of Protection Systems (e.g. pumps, valves, inverter loads), the functional entity may consider additional testing to confirm that the capacity of the battery is sufficient to support all loads.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning; a reading taken from the battery charger panel meter or even SCADA values of the dc voltage could be some of the ways that one could satisfy the requirements. Low battery voltage below float voltage indicates that the battery may be on discharge and, if not corrected, the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. As above, there are many ways that this requirement can be met.

Why check for the electrolyte level?

In vented lead-acid (VLA) and nickel-cadmium (NiCad) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in valve-regulated lead-acid (VRLA) batteries cannot be observed, there is no maintenance activity listed in Table 1-4 of the standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCad station battery is a condition requiring correction. Typically, the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCad) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries, the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery, or other unforeseen events can cause rapid loss of electrolyte; the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

What are the parameters that can be evaluated in Tables 1-4(a) and 1-4(b)?

The most common parameter that is periodically trended and evaluated by industry today to verify that the station battery can perform as manufactured is internal ohmic cell/unit measurements.

In the mid-1990s, several large and small utilities began developing maintenance and testing programs for Protection System station batteries using a condition based maintenance approach of trending internal ohmic measurements to each station battery cell's baseline value. Battery owners use the data collected from this maintenance activity to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test.

Other examples of measurable parameters that can be periodically trended and evaluated for lead acid batteries are cell voltage, float current, connection resistance. However, periodically trending and evaluating cell/unit Ohmic measurements are the most common battery/cell parameters that are evaluated by industry to verify a lead acid battery string can perform as manufactured.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for valve-regulated lead-acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to

measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for vented lead-acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is "…verify that the station battery can perform as manufactured by evaluating the measured cell/unit measurements indicative of battery performance (e.g. internal ohmic values) against the station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. Trending against the baseline of VRLA cells in a battery string is essential to determine the approximate state of health of the battery. Ohmic measurement testing may be used as the mechanism for measuring the battery cells. If all the cells in the string exhibit a consistent trend line and that trend line has not risen above a specific deviation (e.g. 30%) over baseline for impedance tests or below baseline for conductance tests, then a judgment can be made that the battery is still in a reasonably good state of health and able to 'perform as manufactured.' It is essential that the specific deviation mentioned above is based on data (test or otherwise) that correlates the ohmic readings for a specific battery/tester combination to the health of the battery. This is the intent of the "perform **as** manufactured six-month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not necessarily have a formal trending program. When a single cell/unit changes significantly or significantly varies from the other cells (e.g. a doubling of resistance/impedance or a 50% decrease in conductance), there is a high probability that the cell/unit/string needs to be replaced as soon as possible. In other words, if the battery is 10 years old and all the cells have approached a significant change in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery, but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is susceptible to thermal runaway. If the float (charging) current has risen significantly and the ohmic measurement has increased/decreased as described above then concern of catastrophic failure should trigger attention for corrective action.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the six-month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do

the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a six-month basis.

It is possible to accomplish both tasks listed (trend testing for capability and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

In table 1-4(f) (Exclusions for Protection System Station dc Supply Monitoring Devices and Systems), must all component attributes listed in the table be met before an exclusion can be granted for a maintenance activity?

Table 1-4(f) was created by the drafting team to allow Protection System dc supply owners to obtain exclusions from periodic maintenance activities by using monitoring devices. The basis of the exclusions granted in the table is that the monitoring devices must incorporate the monitoring capability of microprocessor based components which perform continuous self-monitoring. For failure of the microprocessor device used in dc supply monitoring, the self-checking routine in the microprocessor must generate an alarm which will be reported within 24 hours of device failure to a location where corrective action can be initiated.

Table 1-4(f) lists 8 component attributes along with a specific periodic maintenance activity associated with each of the 8 attributes listed. If an owner of a station dc supply wants to be excluded from periodically performing one of the 8 maintenance activities listed in table 1-4(f), the owner must have evidence that the monitoring and alarming component attributes associated with the excluded maintenance activity are met by the self-checking microprocessor based device with the specific component attribute listed in the table 1-4(f).

For example if an owner of a VLA station battery does not want to "verify station dc supply voltage" every "4 calendar months" (see table 1-4(a)), the owner can install a monitoring and alarming device "with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure" and "no periodic verification of station dc supply voltage is required" (see table 1-4(f) first row). However, if for the same Protection System discussed above, the owner does not install "electrolyte level monitoring and alarming in every cell" and "unintentional dc ground monitoring and alarming" (see second and third rows of table 1-4(f)), the owner will have to "inspect electrolyte level and for unintentional grounds" every "4 calendar months" (see table 1-4(a)).

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications-assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested. Besides the trip output and wiring to the trip coil(s), there is also a communications medium that must be maintained. Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology. For example, older technologies may have included Frequency Shift Key methods. This technology requires that guard and trip levels be maintained. The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests. Emerging technologies transfer digital information over a variety of carrier mediums that are then

interpreted locally as trip signals. The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore, this standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this standard to require that a test be performed on any communications-assisted trip scheme, regardless of the vintage of technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every four months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements, including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the four-month inspection of communications-assisted trip scheme equipment?

The four-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms; check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e., FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System control circuitry and tested per the portions of Table 1 applicable to "Protection System Control Circuitry", rather than those portions of the table applicable to communications equipment.

What is meant by "Channel" and "Communications Systems" in Table 1-2?

The transmission of logic or data from a relay in one station to a relay in another station for use in a pilot relay scheme will require a communications system of some sort. Typical relay communications systems use fiber optics, leased audio channels, power line carrier, and microwave. The overall communications system includes the channel and the associated communications equipment.

This standard refers to the "channel" as the medium between the transmitters and receivers in the relay panels such as a leased audio or digital communications circuit, power line and power line carrier auxiliary equipment, and fiber. The dividing line between the channel and the associated communications equipment is different for each type of media.

Examples of the Channel:

- Power Line Carrier (PLC) - The PLC channel starts and ends at the PLC transmitter and receiver output unless there is an internal hybrid. The channel includes the external hybrids, tuners, wave traps and the power line itself.
- Microwave –The channel includes the microwave multiplexers, radios, antennae and associated auxiliary equipment. The audio tone and digital transmitters and receivers in the relay panel are the associated communications equipment.
- Digital/Audio Circuit – The channel includes the equipment within and between the substations. The associated communications equipment includes the relay panel transmitters and receivers and the interface equipment in the relays.

- Fiber Optic – The channel starts at the fiber optic connectors on the fiber distribution panel at the local station and goes to the fiber optic distribution panel at the remote substation. The jumpers that connect the relaying equipment to the fiber distribution panel and any optical-electrical signal format converters are the associated communications equipment

Figure 1-2, A-1 and A-2 at the end of this document show good examples of the communications channel and the associated communications equipment.

In Table 1-2, the Maintenance Activities section of the Protection System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria." What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally, an alarm will be indicated. For unmonitored systems, this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each Protection System communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of Protection System communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a Fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the Fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and

set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so Protection System channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria, depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system, then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot, and, thus, make it easier to read the Tables 1-1 through 1-5, Table 3, and Table 4. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a standard alarming system or an auto-polling system; the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours, then it too is considered monitored.

15.6.1 Frequently Asked Questions:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the standard technology neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?

If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center, then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and Distributed UVLS Systems (Table 3)

Distributed UFLS and distributed UVLS systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current-sensing devices have the same maintenance activity and interval as Table 1-3. DC systems need only have their voltage read at the relay every 12 years. Control circuits have the following maintenance activities every 12 years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out and/or auxiliary tripping device(s) used in the trip circuit.
- No verification of trip path required between the lock-out (and/or auxiliary tripping device) and the non-BES interrupting device.
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication systems for distributed UFLS and distributed UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or distributed UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however, the part of the trip path control circuitry between the Load-Shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single transmission Protection System failure, such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just Fault clearing duty; and, therefore, these circuit breakers are operated at least as frequently as any requirements that appear in this standard.

There are times when a Protection System component will be used on a BES device, as well as a non-BES device, such as a battery bank that serves both a BES circuit breaker and a non-BES interrupting device used for UFLS. In such a case, the battery bank (or other Protection System component) will be subject to the Tables of the standard because it is used for the BES.

15.7.1 Frequently Asked Questions:

The standard reaches further into the distribution system than we would like for UFLS and UVLS

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines bulk power system as: "(A) facilities and control Systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition, then, is limited by a later statement which adds the term bulk power system "…does not include facilities used in the local distribution of electric energy." Also, Section 215 also covers users, owners, and operators of bulk power Facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy," despite their location on local distribution networks. Further, if UFLS/UVLS Facilities were not covered by the reliability standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that Load would have to be shed at the Transmission bus to ensure the Load-generation balance and voltage stability is maintained on the BES.

15.8 Automatic Reclosing (Table 4)

Please see the document referenced in Section F of PRC-005-3, "Considerations for Maintenance and Testing of Autoreclosing Schemes — November 2012", for a discussion of Automatic Reclosing as addressed in PRC-005-3.

15.8.1 Frequently-asked Questions

Automatic Reclosing is a control, not a protective function; why then is Automatic Reclosing maintenance included in the Protection System Maintenance Program (PSMP)?

Automatic Reclosing is a control function. The standard's title 'Protection System and Automatic Reclosing Maintenance' clearly distinguishes (separates) the Automatic Reclosing from the Protection System. Automatic Reclosing is included in the PSMP because it is a more pragmatic approach as compared to creating a parallel and essentially identical 'Control System Maintenance Program' for the two Automatic Reclosing component types.

When do I need to have the initial maintenance of Automatic Reclosing Components completed upon change of the largest BES generating unit in the BA/RSG?

The maintenance interval, for newly identified Automatic Reclosing Components, starts when a change in the largest BES generating unit is determined by the BA/RSG. The first maintenance records for newly identified Automatic Reclosing Components should be dated no later than the maximum maintenance interval after the identification date. The maximum maintenance intervals for each newly identified Component are defined in Table 4. No activities or records are required prior to the date of identification.

Our maintenance practice consists of initiating the Automatic Reclosing relay and confirming the breaker closes properly and the close signal is released. This practice verifies the control circuitry associated with Automatic Reclosing. Do you agree?"

The described task partially verifies the control circuit maintenance activity. To meet the control circuit maintenance activity, responsible entities need to verify, *upon initiation*, that the reclosing relay does not issue a *premature closing command*. As noted on page 12 of the SAMS/SPCS report, the concern being addressed within the standard is premature auto reclosing that has the potential to cause generating unit or plant instability. Reclosing applications have many variations, responsible entities will need to verify the applicability of associated supervision/conditional logic and the reclosing relay operation; then verify the conditional logic or that the reclosing relay performs in a manner that does not result in a *premature closing command* being issued.

Some examples of conditions which can result in a premature closing command are: an improper supervision or conditional logic input which provides a false state and allows the reclosing relay to issue an improper close command based on incorrect conditions (i.e. voltage supervision, equipment status, sync window verification); timers utilized for closing actuation or reclosing arming/disarming circuitry which could allow the reclosing relay to issue an improper close command; a reclosing relay output contact failure which could result in a made-up-close condition / failure-to-release condition.

Why was a close-in three phase fault present for twice the normal clearing time chosen for the Automatic Reclosing exclusion? It exceeds TPL requirements and ignores the breaker closing time in a trip-close-trip sequence, thus making the exclusion harder to attain.

This condition represents a situation where a close signal is issued with no time delay or with less time delay than is intended, such as if a reclosing contact is welded closed. This failure mode can result in a minimum trip-close-trip sequence with the two faults cleared in primary protection operating time, and the open time between faults equal to the breaker closing cycle time. The sequence for this failure mode results in system impact equivalent to a high-speed autoreclosing sequence with no delay added in the autoreclosing logic. It represents a failure mode which must be avoided because it exceeds TPL requirements.

Do we have to test the various breaker closing circuit interlocks and controls such as anti-pump?

These components are not specifically addressed within Table 4, and need not be individually tested. They are indirectly verified by performing the Automatic Reclosing control circuitry verification as established in Table 4.

For Automatic Reclosing that <u>is not</u> part of an RAS, do we have to close the circuit breaker periodically?

No. For this application, you need only to verify that the Automatic Reclosing, upon initiation, does not issue a premature closing command. This activity is concerned only with assuring that a premature close does not occur, and cause generating plant instability.

For Automatic Reclosing that <u>is</u> part of an RAS, do we have to close the circuit breaker periodically?

Yes. In this application, successful closing is a necessary portion of the RAS, and must be verified.

Why is maintenance of supervisory relays now included in PRC-005 for Automatic Reclosing?

Proper performance of supervising relays supports the reliability of the BES because some conditions can result in a premature closing command. -An example of this would be an improper supervision or conditional logic input which provides a false state and allows the reclosing relay to issue an improper close command based on incorrect conditions (i.e. voltage supervision, sync window verification)

My reclosing circuitry contains the following inputs listed below; what supervising relays would need to tested per PRC-005?:

- 79/ON – Supervisory contact which turns Automatic reclosing ON or OFF
- 52 – Supervisory contact which provides breaker indication ("b" contact)
- 86 - Supervisory contact from a lockout relay
- 79 – Supervisory contact from a reclosing relay
- 25 – Supervisory contact from a sync-check relay
- 27 or 59 – Supervisory contact from a undervoltage of overvoltage relay

Supervising Relays are defined in this standard as "relay(s) that perform voltage and/or sync check functions that enables or disables operation of the reclosing relay." The 79/ON, 52, and 86 would not need to be included. However, the 79, 25, and 27 or 59 would be included because they are supervisory devices that are either associated with autoreclosing, sync-checks, and/or voltage.

The sync check and voltage check functions are part of my microprocessor reclosing relay. Are there any test requirements for these internal supervisory functions?

A microprocessor reclosing relay that is using internal sync check or voltage check supervisory functions is a combinational reclosing and supervisory relay (i.e. 79/25)-. The maintenance activities for both a reclosing relay and supervisory relay would apply. The voltage sensing devices providing input to a combinational reclosing and supervisory relay would require the activities in Table 4-3.

Is it necessary to verify the close signal operates the breaker?

Only when the control circuitry associated with automatic reclosing is a part of a RAS, then all paths that are essential for proper operation of the RAS must be verified, per table 4-2(b).

15.9 Sudden Pressure Relaying (Table 5)

Please see the document referenced in Section F of PRC-005-4, "Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities – December 2013", for a discussion of Sudden Pressure Relaying as addressed in PRC-005-4.

15.9.1 Frequently Asked Questions:

How do I verify the pressure or flow sensing mechanism is operable?

Maintenance activities for the fault pressure relay associated with Sudden Pressure Relaying in PRC-005-4 are intended to verify that the pressure and/or flow sensing mechanism are functioning correctly. Beyond this, PRC-005-4 requires no calibration (adjusting the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement) or testing (applying signals to a component to observe functional performance or output behavior, or to diagnose problems) activities. For example, some designs of flow sensing mechanisms allow the operation of a test switch to actuate the limit switch of the flow sensing mechanism. Operation of this test switch and verification of the flow sensing mechanism would meet the requirements of the maintenance activity. Another example involves a gas pressure sensing mechanism which is isolated by a test plug. Removal of the plug and verification of the bellows mechanism would meet the requirements of the maintenance activity.

Why the 6-year maximum maintenance interval for fault pressure relays?

The SDT established the six-year maintenance interval for fault pressure relays (see Table 5, PRC-005-4) based on the recommendation of the System Protection and Control Subcommittee (SPCS). The technical experts of the SPCS were tasked with developing the technical documents to:

i. Describe the devices and functions (to include sudden pressure relays which trip for fault conditions) that should address FERC's concern; and

ii. Propose minimum maintenance activities for such devices and maximum maintenance intervals, including the technical basis for each.

Excerpt from the SPCS technical report: "In order to determine present industry practices related to sudden pressure relay maintenance, the SPCS conducted a survey of Transmission Owners and Generator Owners in all eight Regions requesting information related to their maintenance practices. The SPCS received responses from 75 Transmission Owners and 109 Generator Owners. Note that, for the purpose of the survey, sudden pressure relays included the following: the "sudden pressure relay" (SPR) originally manufactured by Westinghouse, the "rapid pressure rise relay" (RPR) manufactured by Qualitrol, and a variety of Buchholz relays.

Table 2 provides a summary of the results of the responses:

Table 2: Sudden Pressure Relay Maintenance Practices – Survey Results

	Transmission Owner	Generator Owner
Number of responding owners that trip with Sudden Pressure Relays:	67	84
Percentage of responding owners who trip that have a Maintenance Program:	75%	78%
Percentage of maintenance programs that include testing the pressure actuator:	81%	77%

Average Maintenance interval reported:	5.9 years	4.9 years

Additionally, in order to validate the information noted above, the SPCS contacted the following entities for their feedback: the IEEE Power System Relaying Committee, the IEEE Transformer Committee, the Doble Transformer Committee, the NATF System Protection Practices Group, and the EPRI Generator Owner/Operator Technical Focus Group. All of these organizations indicated the results of the SPCS survey are consistent with their respective experiences.

The SPCS discussed the potential difference between the recommended intervals for fault pressure relaying and intervals for transformer maintenance. The SPCS developed the recommended intervals for fault pressure relaying by comparing fault pressure relaying to Protection System Components with similar physical attributes. The SPCS recognized that these intervals may be shorter than some existing or future transformer maintenance intervals, but believed it to be more important to base intervals for fault pressure relaying on similar Protection System Components than transformer maintenance intervals.

The maintenance interval for fault pressure relays can be extended by utilizing performance-based maintenance thereby allowing entities that have maintenance intervals for transformers in excess of six years, to align them.

Sudden Pressure Relaying control circuitry is now specifically mentioned in the maintenance tables. Do we have to trip our circuit breaker specifically from the trip output of the sudden pressure relay?

No. Verification may be by breaker tripping, but may be verified in overlapping segments with the Protection System control circuitry.

Can we use Performance Based Maintenance for fault pressure relays?

Yes. Performance Based Maintenance is applicable to fault pressure relays.

15.10 Examples of Evidence of Compliance

To comply with the requirements of this standard, an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC standards that could, at times, fulfill evidence requirements of this standard.

15.10.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the requirement being documented include, but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records

- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-4?

Maintaining evidence for operation of Remedial Action Schemes could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus, the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-4.

I maintain Disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications, to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

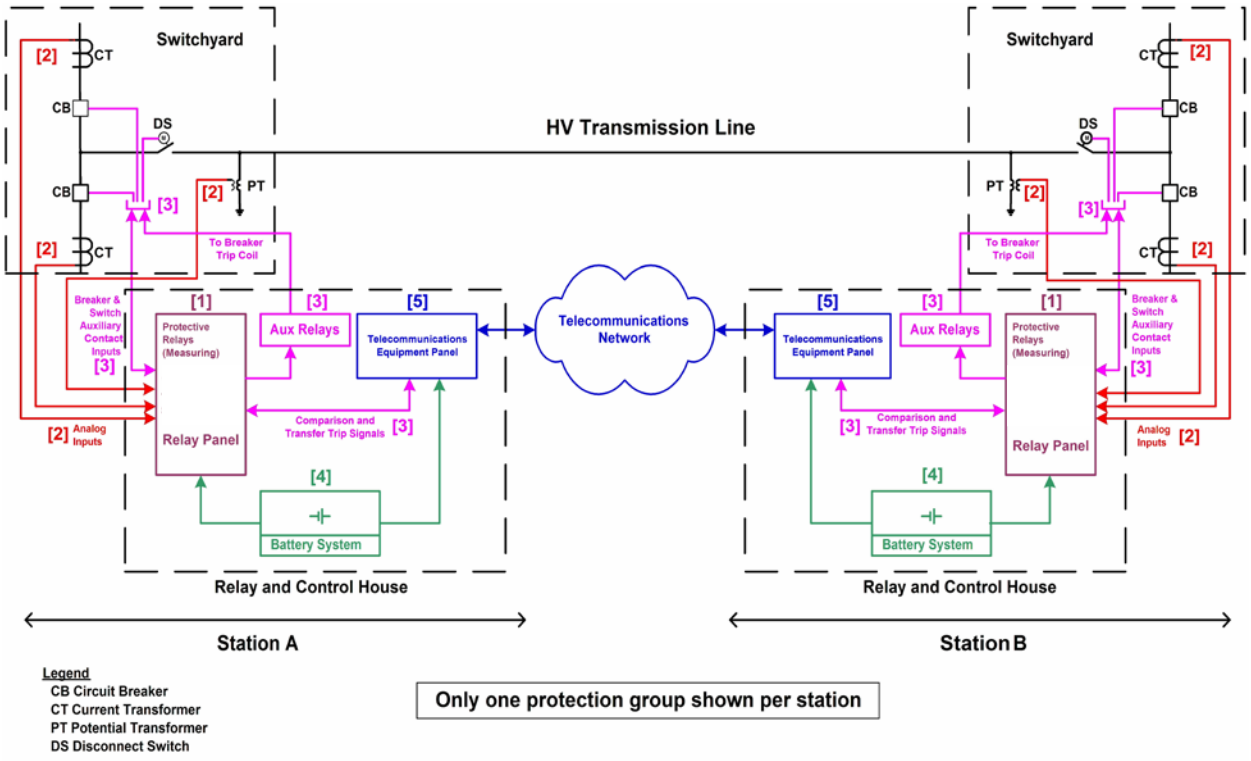
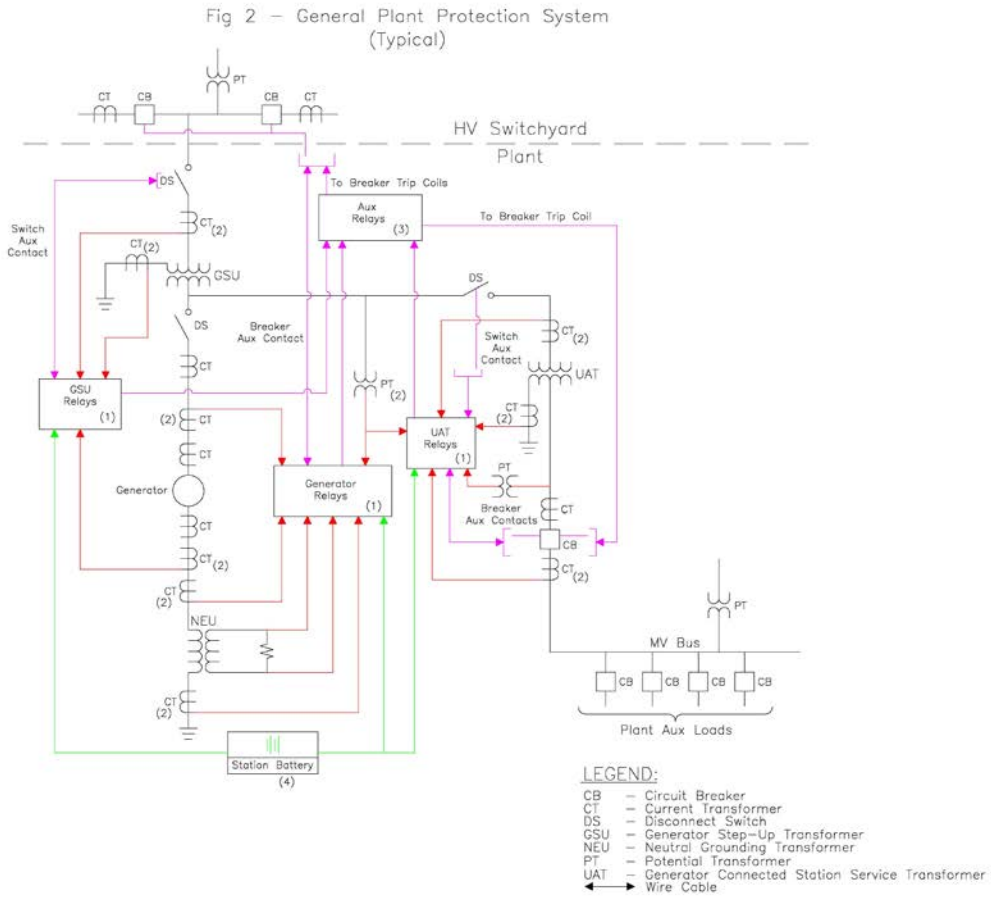
Figure 1: Typical Transmission System



For information on components, see ***Figure 1 & 2 Legend – components of Protection Systems***

Figure 2: Typical Generation System



Note: Figure 2 may show elements that are not included within PRC-005-2, and also may not be all-inclusive; see the Applicability section of the standard for specifics.

For information on components, see ***Figure 1 & 2 Legend – components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including ~~sync-check systems~~, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

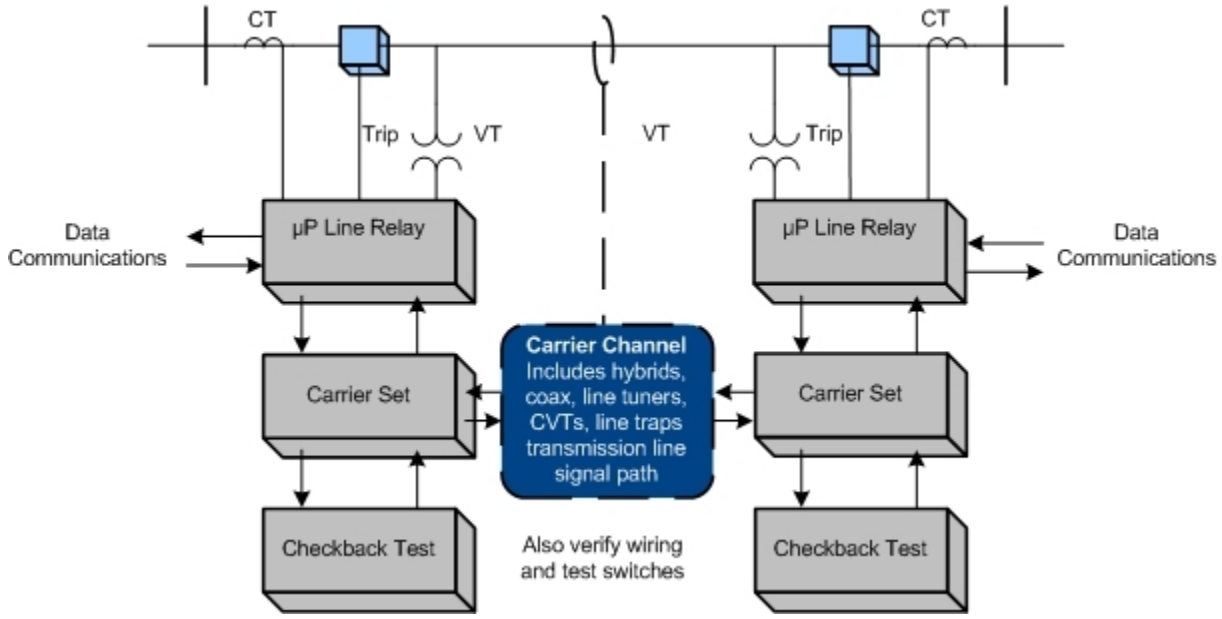
Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line Faults, and to avoid over-tripping for Faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

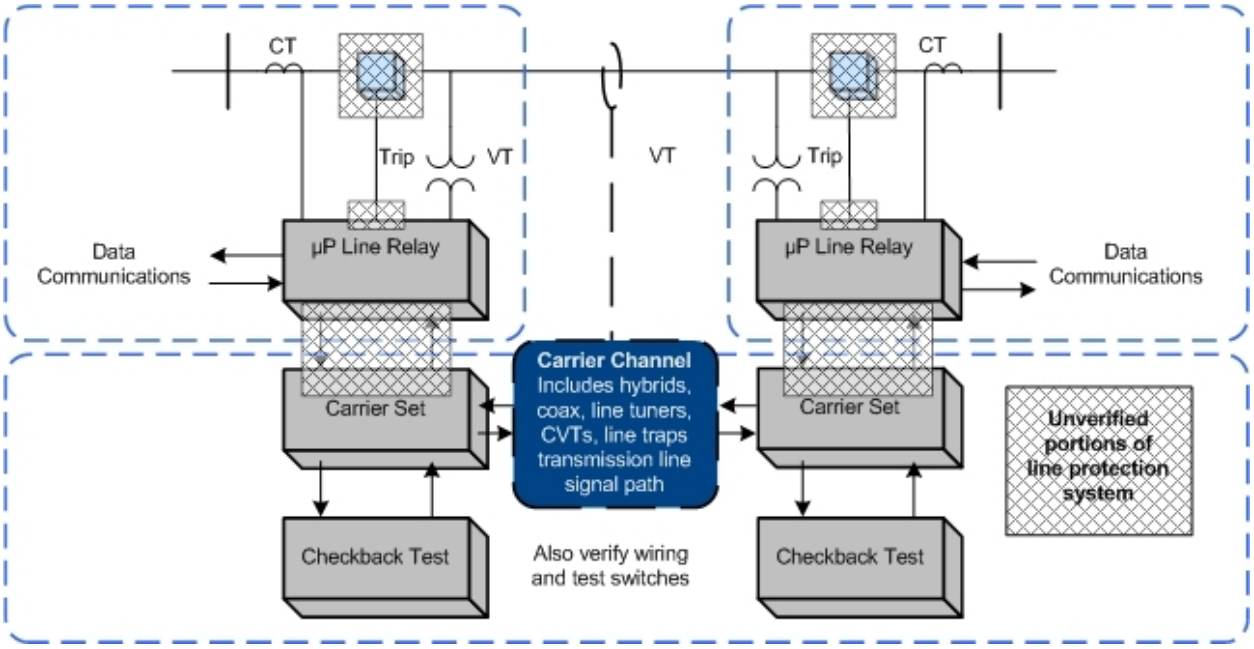
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies voltage & current sensing devices, wiring, and analog signal input processing of the relays. One

effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a Fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring Faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If Faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005-4 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated Fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring Faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

1. Introduction and Summary

Note: This supplementary reference for PRC-005-4 is neither mandatory nor enforceable.

NERC currently has four Reliability Standards that are mandatory and enforceable in the United States and Canada and address various aspects of maintenance and testing of Protection and Control Systems.

These standards are:

PRC-005-1b — Transmission and Generation Protection System Maintenance and Testing

PRC-008-0 — Underfrequency Load Shedding Equipment Maintenance Programs

PRC-011-0 — UVLS System Maintenance and Testing

PRC-017-0 — Special Protection System Maintenance and Testing

While these standards require that applicable entities have a maintenance program for Protection Systems, and that these entities must be able to demonstrate they are carrying out such a program, there are no specifics regarding the technical requirements for Protection System maintenance programs. Furthermore, FERC Order 693 directed additional modifications respective to Protection System maintenance programs. PRC-005-3 will replace PRC-005-2 which combined and replaced PRC-005, PRC-008, PRC-011 and PRC-017. PRC-005-3 adds Automatic Reclosing to PRC-005-2. PRC-005-2 addressed these directed modifications and replaces PRC-005, PRC-008, PRC-011 and PRC-017.

FERC Order 758 further directed that maintenance of reclosing relays and sudden pressure relays that affect the reliable operation of the Bulk Power System be addressed. PRC-005-3 addresses this directive regarding reclosing relays, and, when approved, will supersede PRC-005-2. PRC-005-4 addresses this directive regarding sudden pressure relays and, when approved, will supersede PRC-005-3.

This document augments the Supplementary Reference and FAQ previously developed for PRC-005-2 by including discussion relevant to Automatic Reclosing added in PRC-005-3 and Sudden Pressure Relaying in PRC-005-4.

2. Need for Verifying Protection System Performance

Protective relays have been described as silent sentinels, and do not generally demonstrate their performance until a Fault or other power system problem requires that they operate to protect power system Elements, or even the entire Bulk Electric System (BES). Lacking Faults, switching operations or system problems, the Protection Systems may not operate, beyond static operation, for extended periods. A Misoperation - a false operation of a Protection System or a failure of the Protection System to operate, as designed, when needed - can result in equipment damage, personnel hazards, and wide-area Disturbances or unnecessary customer outages. Maintenance or testing programs are used to determine the performance and availability of Protection Systems.

Typically, utilities have tested Protection Systems at fixed time intervals, unless they had some incidental evidence that a particular Protection System was not behaving as expected. Testing practices vary widely across the industry. Testing has included system functionality, calibration of measuring devices, and correctness of settings. Typically, a Protection System must be visited at its installation site and, in many cases, removed from service for this testing.

Fundamentally, a Reliability Standard for Protection System Maintenance and Testing requires the performance of the maintenance activities that are necessary to detect and correct plausible age and service related degradation of the Protection System components, such that a properly built and commissioned Protection System will continue to function as designed over its service life.

Similarly station batteries, which are an important part of the station dc supply, are not called upon to provide instantaneous dc power to the Protection System until power is required by the Protection System to operate circuit breakers or interrupting devices to clear Faults or to isolate equipment.

2.1 Existing NERC Standards for Protection System Maintenance and Testing

For critical BES protection functions, NERC standards have required that each utility or asset owner define a testing program. The starting point is the existing Standard PRC-005, briefly restated as follows:

Purpose: To document and implement programs for the maintenance of all Protection Systems affecting the reliability of the Bulk Electric System (BES) so that these Protection Systems are kept in working order.

PRC-005-4 is not specific on where the boundaries of the Protection Systems lie. However, the definition of Protection System in the NERC Glossary of Terms used in Reliability Standards indicates what must be included as a minimum.

At the beginning of the project to develop PRC-005-2, the definition of Protection System was:

Protective relays, associated communications Systems, voltage and current sensing devices, station batteries and dc control circuitry.

Applicability: Owners of generation and transmission Protection Systems.

Requirements: The owner shall have a documented maintenance program with test intervals. The owner must keep records showing that the maintenance was performed at the specified intervals.

2.2 Protection System Definition

The most recently approved definition of Protection Systems is:

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

2.3 Applicability of New Protection System Maintenance Standards

The BES purpose is to transfer bulk power. The applicability language has been changed from the original PRC-005:

"*...affecting the reliability of the Bulk Electric System (BES)…*"

To the present language:

"*…that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.).*"

The drafting team intends that this standard will follow with any definition of the Bulk Electric System. There should be no ambiguity; if the Element is a BES Element, then the Protection System protecting that Element should then be included within this standard. If there is regional variation to the definition, then there will be a corresponding regional variation to the Protection Systems that fall under this standard.

There is no way for the Standard Drafting Team to know whether a specific 230KV line, 115KV line (even 69KV line), for example, should be included or excluded. Therefore, the team set the clear intent that the standard language should simply be applicable to Protection Systems for BES Elements.

The BES is a NERC defined term that, from time to time, may undergo revisions. Additionally, there may even be regional variations that are allowed in the present and future definitions. See the NERC Glossary of Terms for the present, in-force definition. See the applicable Regional Reliability Organization for any applicable allowed variations.

While this standard will undergo revisions in the future, this standard will not attempt to keep up with revisions to the NERC definition of BES, but, rather, simply make BES Protection Systems applicable.

The Standard is applied to Generator Owners (GO) and Transmission Owners (TO) because GOs and TOs have equipment that is BES equipment. The standard brings in Distribution Providers (DP) because, depending on the station configuration of a particular substation, there may be

Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-4 would apply to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

PRC-005-2 replaced the existing PRC-005, PRC-008, PRC-011 and PRC-017. Much of the original intent of those standards was carried forward whenever it was possible to continue the intent without a disagreement with FERC Order 693. For example, the original PRC-008 was constructed quite differently than the original PRC-005. The drafting team agrees with the intent of this and notes that distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a transmission Protection System Bus Differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as stipulated in any requirement in this standard.

Additionally, since PRC-005-2 replaced PRC-011, it will be important to make the distinction between under-voltage Protection Systems that protect individual Loads and Protection Systems that are UVLS schemes that protect the BES. Any UVLS scheme that had been applicable under PRC-011 is now applicable under PRC-005-2. An example of an under-voltage load-shedding scheme that is not applicable to this standard is one in which the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission system that was intact except for the line that was out of service, as opposed to preventing a Cascading outage or Transmission system collapse.

It had been correctly noted that the devices needed for PRC-011 are the very same types of devices needed in PRC-005.

Thus, a standard written for Protection Systems of the BES can easily make the needed requirements for Protection Systems, and replace some other standards at the same time.

2.3.1 Frequently Asked Questions:

What exactly is the BES, or Bulk Electric System?

BES is the abbreviation for Bulk Electric System. BES is a term in the Glossary of Terms used in Reliability Standards, and is not being modified within this draft standard.

Why is Distribution Provider included within the Applicable Entities and as a responsible entity within several of the requirements? Wouldn't anyone having relevant Facilities be a Transmission Owner?

Depending on the station configuration of a particular substation, there may be Protection System equipment installed at a non-transmission voltage level (Distribution Provider equipment) that is wholly or partially installed to protect the BES. PRC-005-4 applies to this equipment. An example is underfrequency load-shedding, which is frequently applied well down into the distribution system to meet PRC-007-0.

We have an under voltage load-shedding (UVLS) system in place that prevents one of our distribution substations from supplying extremely low voltage in the case of a specific transmission line outage. The transmission line is part of the BES. Does this mean that our UVLS system falls within this standard?

The situation, as stated, indicates that the tripping action was intended to prevent low distribution voltage to a specific Load from a Transmission System that was intact, except for the line that was out of service, as opposed to preventing Cascading outage or Transmission System Collapse.
This standard is not applicable to this UVLS.

We have a UFLS or UVLS scheme that sheds the necessary Load through distribution-side circuit breakers and circuit reclosers. Do the trip-test requirements for circuit breakers apply to our situation?

No. Distributed tripping schemes would have to exhibit multiple failures to trip before they would prove to be significant, as opposed to a single failure to trip of, for example, a transmission Protection System bus differential lock-out relay. While many failures of these distribution breakers could add up to be significant, it is also believed that distribution breakers are operated often on just Fault clearing duty; and, therefore, the distribution circuit breakers are operated at least as frequently as any requirements that might have appeared in this standard.

We have a UFLS scheme that, in some locales, sheds the necessary Load through non-BES circuit breakers and, occasionally, even circuit switchers. Do the trip-test requirements for circuit breakers apply to our situation?

If your "non-BES circuit breaker" has been brought into this standard by the inclusion of UFLS requirements, and otherwise would not have been brought into this standard, then the answer is that there are no trip-test requirements. For these devices that are otherwise non-BES assets, these tripping schemes would have to exhibit multiple failures to trip before they would prove to be as significant as, for example, a single failure to trip of a transmission Protection System bus differential lock-out relay.

How does the "Facilities" section of "Applicability" track with the standards that will be retired once PRC-005-2 becomes effective?

In establishing PRC-005-2, the drafting team combined legacy standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0. The merger of the subject matter of these standards is reflected in Applicability 4.2.

The intent of the drafting team is that the legacy standards be reflected in PRC-005-2 as follows:

- Applicability of PRC-005-1b for Protection Systems relating to non-generator elements of the BES is addressed in 4.2.1;
- Applicability of PRC-008-0 for underfrequency load shedding systems is addressed in 4.2.2;
- Applicability of PRC-011-0 for undervoltage load shedding relays is addressed in 4.2.3;
- Applicability of PRC-017-0 for Remedial Action Schemes is addressed in 4.2.4;
- Applicability of PRC-005-1b for Protection Systems for BES generators is addressed in 4.2.5 and 4.2.6.

2.4 Applicable Relays

The NERC Glossary definition has a Protection System including relays, dc supply, current and voltage sensing devices, dc control circuitry and associated communications circuits. The relays to which this standard applies are those protective relays that respond to electrical quantities and provide a trip output to trip coils, dc control circuitry or associated communications equipment. This definition extends to IEEE Device No. 86 (lockout relay) and IEEE Device No. 94 (tripping or trip-free relay), as these devices are tripping relays that respond to the trip signal of the protective relay that processed the signals from the current and voltage-sensing devices.

Relays that respond to non-electrical inputs or impulses (such as, but not limited to, vibration, seismic, thermal or gas accumulation) are not included.

Automatic Reclosing is addressed in PRC-005-3 by explicitly addressing them outside the definition of Protection System. The specific locations for applicable Automatic Reclosing are addressed in Applicability Section 4.2.7.

Sudden Pressure Relaying is addressed in PRC-005-4 by explicitly addressing them outside the definition of Protection System. The specific locations for applicable Sudden Pressure Relaying are addressed in Applicability Section 4.2.1, 4.2.5.2, 4.2.5.3, and 4.2.6.

2.4.1 Frequently Asked Questions:

Are power circuit reclosers, reclosing relays, closing circuits and auto-restoration schemes covered in this Standard?

Yes. Automatic Reclosing includes reclosing relays and the associated dc control circuitry. Section 4.2.7 of the Applicability specifically limits the applicable reclosing relays to:

4.2.7 Automatic Reclosing

4.2.7.1 Automatic Reclosing applied on the terminals of Elements connected to the BES bus located at generating plant substations where the total installed gross generating plant capacity is greater than the gross capacity of the largest BES generating unit within the Balancing Authority Area or, if a member of a Reserve Sharing Group, the largest generating unit within the Reserve Sharing Group.

4.2.7.2 Automatic Reclosing applied on the terminals of all BES Elements at substations one bus away from generating plants specified in Section 4.2.7.1 when the substation is less than 10 circuit-miles from the generating plant substation.

4.2.7.3 Automatic Reclosing applied as an integral part of an RAS specified in Section 4.2.4.

Further, Footnote 1 to Applicability Section 4.2.7 establishes that Automatic Reclosing addressed in 4.2.7.1 and 4.2.7.2 may be excluded if the equipment owner can demonstrate that a close-in three-phase fault present for twice the normal clearing time (capturing a minimum trip-close-trip time delay) does not result in a total loss of gross generation in the Interconnection exceeding the gross capacity of the largest relevant BES generating unit where the Automatic Reclosing is applied.

Additionally, Footnote 2 to Applicability Section 4.2.7.1 advises that the entity's PSMP needs to remain current regarding the applicability of Automatic Reclosing Components relative to the largest generating unit within the Balancing Authority Area or Reserve Sharing Group.

The Applicability as detailed above was recommended by the NERC System Analysis and Modeling Subcommittee (SAMS) after a lengthy review of the use of reclosing within the BES. SAMS concluded that automatic reclosing is largely implemented throughout the BES as an operating convenience, and that automatic reclosing mal-performance affects BES reliability only when the reclosing is part of a Remedial Action Schemes, or when premature autoreclosing has the potential to cause generating unit or plant instability. A technical report, "Considerations for Maintenance and Testing of Autoreclosing Schemes — November 2012", is referenced in PRC-005-3 and provides a more detailed discussion of these concerns.

Why did the standard drafting team not include IEEE device numbers to describe Automatic Reclosing Relays?

The drafting team elected not to include IEEE device numbers to describe Automatic Reclosing because Automatic Reclosing component type could be a stand-alone electromechanical relay; or could be the 79 function within a microprocessor based multi-function relay(11).

What is synchronizing or synchronism check relay (Sync-Check - 25)?

A synchronizing device that produces an output that supervises closure of a circuit breaker between two circuits whose voltages are within prescribed limits of magnitude and phase angle. It may or may not include voltage or speed control. A sync-check relay permits the paralleling of two circuits that are within prescribed (usually wider) limits of voltage magnitude and phase angle.

How do I interpret Applicability Section 4.2.7 to determine applicability in the following examples:

At my generating plant substation, I have a total of 800 MW connected to one voltage level and 200 MW connected to another voltage level. How do I determine my gross capacity? Where do I consider Automatic Reclosing to be applicable?

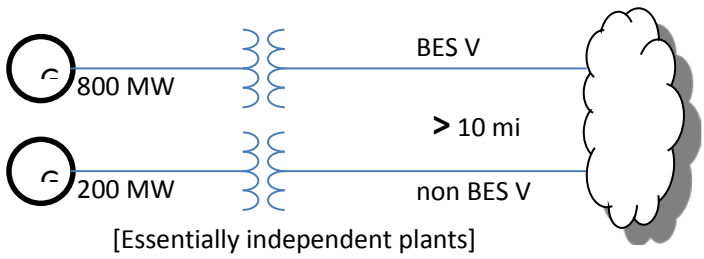
Scenario number 1:

The 800 MW of generation is connected to a BES voltage level bus, the 200 MW

is connected to a non-BES voltage level bus, and there is no connection between the two buses locally or within 10 circuit miles from the generating plant substation. The largest single unit in the BA area is 750 MW.

In this case, the total installed gross generating capacity would be 800 MW. The two units are essentially independent plants.

The BES voltage level bus is considered to be the bus to which the 800 MW of generation is connected. Any BES Automatic Reclosing at this location, as well as other locations within 10 circuit miles, is considered to be applicable because 800 MW exceeds the largest single unit in the BA area.



[Essentially independent plants]

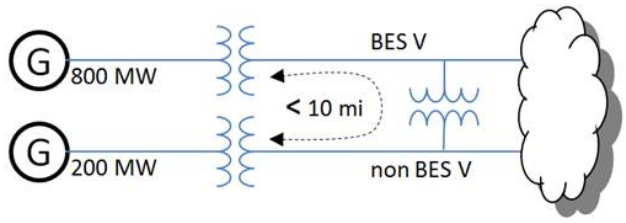
Gross Capacity	**Automatic Reclosing in scope**
800 MW	BES V

Scenario number 2:

The 800 MW of generation is connected to a BES voltage level bus, the 200 MW unit is connected to a non-BES voltage level bus, and there is a connection between the two buses locally or within 10 circuit miles from the generating plant substation. The largest single unit in the BA area is 750 MW.

In this case, reclosing into a fault on the BES system could impact the stability of the non-BES-connected generating units. Therefore, the total installed gross generating capacity would be 1000 MW.

The BES voltage level bus is considered to be the bus to which the 800 MW of generation is connected. Any BES Automatic Reclosing at this location, as well as other locations within 10 circuit miles, is considered to be applicable because total of 1000 MW exceeds the largest single unit in the BA area. However, the Automatic Reclosing on the non-BES voltage level bus is not applicable.



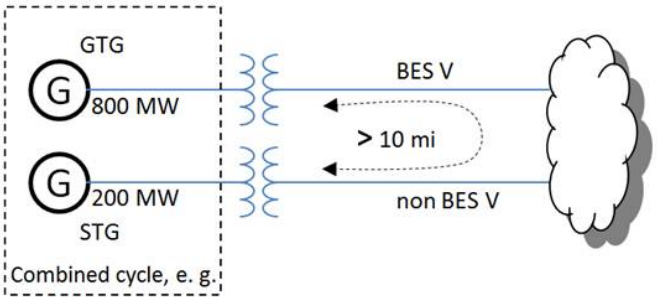
Gross Capacity	**Automatic Reclosing in scope**
1000 MW	BES V

Scenario number 3:

The 800 MW of generation is connected to a BES voltage level bus, the 200 MW unit is connected to a non-BES voltage level bus, and there is no connection between the two buses locally or within 10 circuit miles from the generating plant substation but the generating units connected at the BES voltage level do not operate independently of the units connected at the non BES voltage level (e.g., a combined cycle facility where 800 MW of combustion turbines are connected at a BES voltage level whose exhaust is used to power a 200 MW steam unit connected to a non BES voltage level. The largest single unit in the BA area is 750 MW.

In this case, the total installed gross generating capacity would be 1000 MW. Therefore, reclosing into a fault on the BES voltage level would result in a loss of the 800 MW combustion turbines and subsequently result in the loss of the 200 MW steam unit because of the loss of the heat source to its boiler.

The BES voltage level bus is considered to be the bus to which the 800 MW of generation is connected. Any BES Automatic Reclosing at this location, as well as other locations within 10 circuit miles, is considered to be applicable because total of 1000 MW exceeds the largest single unit in the BA area. However, the Automatic Reclosing on the non-BES voltage level bus is not applicable.



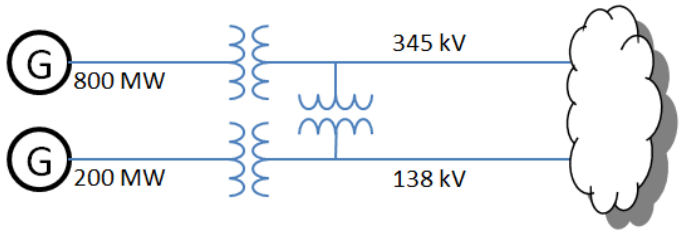
Gross Capacity	**Automatic Reclosing in scope**
1000 MW	BES V

Scenario 4

The 800 MW of generation is connected at 345 kV and the 200 MW is connected at 138 kV with an autotransformer at the generating plant substation connecting the two voltage levels. The largest single unit in the BA area is 900 MW.

In this case, the total installed gross generating capacity would be 1000 MW and section 4.2.7.1 would be applicable to both the 345 kV Automatic Reclosing Components and the 138 kV Automatic Reclosing Components, since the total capacity of 1000 MW is larger than the largest single unit in the BA area.

However, if the 345 kV and the 138 kV systems can be shown to be uncoupled such that the 138 kV reclosing relays will not affect the stability of the 345 kV generating units then the 138 kV Automatic Reclosing Components need not be included per section 4.2.7.1.



Gross Capacity	**Automatic Reclosing in scope**
1000 MW	BOTH*

* The study detailed in Footnote 1 of the draft standard may eliminate the 138 kV Automatic Reclosing Components and/or the 345 kV Automatic Reclosing Components

Why does 4.2.7.2 specify "10 circuit miles"?

As noted in "Considerations for Maintenance and Testing of Autoreclosing Schemes — November 2012", transmission line impedance on the order of one mile away typically provides adequate impedance to prevent generating unit instability and a 10 mile threshold provides sufficient margin.

Should I use MVA or MW when determining the installed gross generating plant capacity?

Be consistent with the rating used by the Balancing Authority for the largest BES generating unit within their area.

What value should we use for generating plant capacity in 4.2.7.1?

Use the value reported to the Balance Authority for generating plant capacity for planning and modeling purposes. This can be nameplate or other values based on generating plant limitations such as boiler or turbine ratings.

What is considered to be "one bus away" from the generation?

The BES voltage level bus is considered to be the generating plant substation bus to which the generator step-up transformer is connected. "One bus away" is the next bus, connected by either a transmission line or transformer.

I use my protective relays only as sources of metered quantities and breaker status for SCADA and EMS through a substation distributed RTU or data concentrator to the control center. What are the maintenance requirements for the relays?

This standard addresses Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.). Protective relays, providing only the functions mentioned in the question, are not included.

Are Reverse Power Relays installed on the low-voltage side of distribution banks considered to be components of "Protection Systems that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)"?

Reverse power relays are often installed to detect situations where the transmission source becomes de-energized and the distribution bank remains energized from a source on the low-voltage side of the transformer and the settings are calculated based on the charging current of the transformer from the low-voltage side. Although these relays may operate as a result of a fault on a BES element, they are not 'installed for the purpose of detecting' these faults.

Why is the maintenance of Sudden Pressure Relaying being addressed in PRC-005-4?

Proper performance of Sudden Pressure Relaying supports the reliability of the BES because fault pressure relays can detect rapid changes in gas pressure, oil pressure, or oil flow that are indicative of faults within liquid-filled, wire-wound equipment such as turn-to-turn faults which may be undetected by Protection Systems. Additionally, Sudden Pressure

Relaying can quickly detect faults and operate to limit damage to liquid-filled, wire-wound equipment.

What type of devices are classified as fault pressure relay?

There are three main types of fault pressure relays; rapid gas pressure rise, rapid oil pressure rise, and rapid oil flow devices.

Rapid gas pressure devices monitor the pressure in the space above the oil (or other liquid), and initiate tripping action for a rapid rise in gas pressure resulting from the rapid expansion of the liquid caused by a fault. The sensor is located in the gas space.

Rapid oil pressure devices monitor the pressure in the oil (or other liquid), and initiate tripping action for a rapid pressure rise caused by a fault. The sensor is located in the liquid.

Rapid oil flow devices ("Buchholz") monitor the liquid flow between a transformer/reactor and its conservator. Normal liquid flow occurs continuously with ambient temperature changes and with internal heating from loading and does not operate the rapid oil flow device. However, when an internal arc happens a sudden expansion of liquid can be monitored as rapid liquid flow from the transformer into the conservator resulting in actuation of the rapid oil flow device.

Are sudden pressure relays that only initiate an alarm included in the scope of PRC-005-4?

No, the definition of Sudden Pressure Relaying specifies only those that trip an interrupting device(s) to isolate the equipment it is monitoring.

Are pressure relief devices included in the scope of PRC-005-4?

No. PRDs are not included in the Sudden Pressure Relaying definition.

Is Sudden Pressure Relaying installed on distribution transformers included in PRC-005-4?

No, Applicability 4.2.1, 4.2.5, and 4.2.6, explicitly describes what Sudden Pressure Relaying is included within the standard.

Are non-electrical sensing devices (other than fault pressure relays) such as low oil level or high winding temperatures included in PRC-005-4?

No, based on the SPCS technical document, "Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities – December 2013," the only applicable non-electrical sensing devices are Sudden Pressure Relays.

The standard specifically mentions auxiliary and lock-out relays. What is an auxiliary tripping relay?

An auxiliary relay, IEEE Device No. 94, is described in IEEE Standard C37.2-2008 as: "A device that functions to trip a circuit breaker, contactor, or equipment; to permit immediate tripping by other devices; or to prevent immediate reclosing of a circuit interrupter if it should open automatically, even though its closing circuit is maintained closed."

What is a lock-out relay?

A lock-out relay, IEEE Device No. 86, is described in IEEE Standard C37.2 as: “A device that trips and maintains the associated equipment or devices inoperative until it is reset by an operator, either locally or remotely.”

3. Protection System and Automatic Reclosing Product Generations

The likelihood of failure and the ability to observe the operational state of a critical Protection System and Automatic Reclosing both depend on the technological generation of the relays, as well as how long they have been in service. Unlike many other transmission asset groups, protection and control systems have seen dramatic technological changes spanning several generations. During the past 20 years, major functional advances are primarily due to the introduction of microprocessor technology for power system devices, such as primary measuring relays, monitoring devices, control Systems, and telecommunications equipment.

Modern microprocessor-based relays have six significant traits that impact a maintenance strategy:

- Self-monitoring capability - the processors can check themselves, peripheral circuits, and some connected substation inputs and outputs, such as trip coil continuity. Most relay users are aware that these relays have self-monitoring, but are not focusing on exactly what internal functions are actually being monitored. As explained further below, every element critical to the Protection System must be monitored, or else verified periodically.
- Ability to capture Fault records showing how the Protection System responded to a Fault in its zone of protection, or to a nearby Fault for which it is required not to operate.
- Ability to meter currents and voltages, as well as status of connected circuit breakers, continuously during non-Fault times. The relays can compute values, such as MW and MVAR line flows, that are sometimes used for operational purposes, such as SCADA.
- Data communications via ports that provide remote access to all of the results of Protection System monitoring, recording and measurement.
- Ability to trip or close circuit breakers and switches through the Protection System outputs, on command from remote data communications messages, or from relay front panel button requests.
- Construction from electronic components, some of which have shorter technical life or service life than electromechanical components of prior Protection System generations.

There have been significant advances in the technology behind the other components of Protection Systems. Microprocessors are now a part of battery chargers, associated communications equipment, voltage and current-measuring devices, and even the control circuitry (in the form of software-latches replacing lock-out relays, etc.).

Any Protection System component can have self-monitoring and alarming capability, not just relays. Because of this technology, extended time intervals can find their way into all components of the Protection System.

This standard also recognizes the distinct advantage of using advanced technology to justifiably defer or even eliminate traditional maintenance. Just as a hand-held calculator does not require routine testing and calibration, neither does a calculation buried in a microprocessor-based device that results in a "lock-out." Thus, the software-latch 86 that replaces an electro-mechanical 86 does not require routine trip testing. Any trip circuitry associated with the "soft 86" would still need applicable verification activities performed, but the actual "86" does not have to be "electrically operated" or even toggled.

4. Definitions

Protection System Maintenance Program (PSMP) — An ongoing program by which Protection System, Automatic Reclosing and Sudden Pressure Relaying Components are kept in working order and proper operation of malfunctioning Components is restored. A maintenance program for a specific Component includes one or more of the following activities:

- Verify — Determine that the Component is functioning correctly.
- Monitor — Observe the routine in-service operation of the Component.
- Test — Apply signals to a Component to observe functional performance or output behavior, or to diagnose problems.
- Inspect — Examine for signs of Component failure, reduced performance and degradation.
- Calibrate — Adjust the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement.

Automatic Reclosing – Includes the following Components:

- Reclosing relay
- Supervisory relay(s) – relay(s) that perform voltage and/or sync check functions that enables or disables operation of the reclosing relay
- Voltage sensing devices associated with the supervisory relay(s)
- Control circuitry associated with the reclosing relay or supervisory relay(s)

Sudden Pressure Relaying – A system that trips an interrupting device(s) to isolate the equipment it is monitoring and includes the following Components:

- Fault pressure relay – a mechanical relay or device that detects rapid changes in gas pressure, oil pressure, or oil flow that are indicative of faults within liquid-filled, wire-wound equipment
- Control circuitry associated with a fault pressure relay

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual Components.

Component Type –

- Any one of the five specific elements of a Protection System.
- Any one of the four specific elements of Automatic Reclosing.
- Any one of the two specific elements of Sudden Pressure Relaying.

Component – Any individual discrete piece of equipment included in a Protection System, Automatic Reclosing, or Sudden Pressure Relaying.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-3, and Table 5, which requires corrective action or a Protection System Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component, Automatic Reclosing or Sudden Pressure Relaying configuration or application errors are not included in Countable Events.

4.1 Frequently Asked Questions:

Why does PRC-005-4 not specifically require maintenance and testing procedures, as reflected in the previous standard, PRC-005-1?

PRC-005-1 does not require detailed maintenance and testing procedures, but instead requires summaries of such procedures, and is not clear on what is actually required. PRC-005-4 requires a documented maintenance program, and is focused on establishing requirements rather than prescribing methodology to meet those requirements. Between the activities identified in the Tables 1-1 through 1-5, Table 2, Table 3, and Table 4 (collectively the "Tables"), and the various components of the definition established for a "Protection System Maintenance Program," PRC-005-4 establishes the activities and time basis for a Protection System Maintenance Program to a level of detail not previously required.

Please clarify what is meant by "restore" in the definition of maintenance.

The description of "restore" in the definition of a Protection System Maintenance Program addresses corrective activities necessary to assure that the component is returned to working order following the discovery of its failure or malfunction. The Maintenance Activities specified in the Tables do not present any requirements related to Restoration; R5 of the standard does require that the entity "shall demonstrate efforts to correct any identified Unresolved Maintenance Issues." Some examples of restoration (or correction of Unresolved Maintenance Issues) include, but are not limited to, replacement of capacitors in distance relays to bring them to working order; replacement of relays, or other Protection System components, to bring the Protection System to working order; upgrade of electromechanical or solid-state protective relays to microprocessor-based relays following the discovery of failed components. Restoration, as used in this context, is not to be confused with restoration rules as used in system operations. Maintenance activity necessarily includes both the detection of problems and the repairs needed to eliminate those problems. This standard does not identify all of the Protection System problems that must be detected and eliminated, rather it is the intent of this standard that an entity determines the necessary working order for their various devices, and keeps them in working order. If an equipment item is repaired or replaced, then the entity can restart the maintenance-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades

might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

Please clarify what is meant by "...demonstrate efforts to correct an Unresolved Maintenance Issue..."; why not measure the completion of the corrective action?

Management of completion of the identified Unresolved Maintenance Issue is a complex topic that falls outside of the scope of this standard. There can be any number of supply, process and management problems that make setting repair deadlines impossible. The SDT specifically chose the phrase "demonstrate efforts to correct" (with guidance from NERC Staff) because of the concern that many more complex Unresolved Maintenance Issues might require greater than the remaining maintenance interval to resolve (and yet still be a "closed-end process"). For example, a problem might be identified on a VRLA battery during a six-month check. In instances such as one that requiring battery replacement as part of the long-term resolution, it is highly unlikely that the battery could be replaced in time to meet the six-calendar-month requirement for this maintenance activity. The SDT does not believe entities should be found in violation of a maintenance program requirement because of the inability to complete a remediation program within the original maintenance interval. The SDT does believe corrective actions should be timely, but concludes it would be impossible to postulate all possible remediation projects; and, therefore, impossible to specify bounding time frames for resolution of all possible Unresolved Maintenance Issues, or what documentation might be sufficient to provide proof that effective corrective action is being undertaken.

5. Time-Based Maintenance (TBM) Programs

Time-based maintenance is the process in which Protection System, Automatic Reclosing and Sudden Pressure Relaying Components are maintained or verified according to a time schedule. The scheduled program often calls for technicians to travel to the physical site and perform a functional test on Protection System components. However, some components of a TBM program may be conducted from a remote location - for example, tripping a circuit breaker by communicating a trip command to a microprocessor relay to determine if the entire Protection System tripping chain is able to operate the breaker. Similarly, all Protection System, and Sudden Pressure Relaying Components can have the ability to remotely conduct tests, either on-command or routinely; the running of these tests can extend the time interval between hands-on maintenance activities.

5.1 Maintenance Practices

Maintenance and testing programs often incorporate the following types of maintenance practices:

- TBM – time-based maintenance – externally prescribed maximum maintenance or testing intervals are applied for components or groups of components. The intervals may have been developed from prior experience or manufacturers' recommendations. The TBM verification interval is based on a variety of factors, including experience of the particular asset owner, collective experiences of several asset owners who are members of a country or regional council, etc. The maintenance intervals are fixed and may range in number of months or in years.

  TBM can include review of recent power system events near the particular terminal. Operating records may verify that some portion of the Protection System has operated correctly since the last test occurred. If specific protection scheme components have demonstrated correct performance within specifications, the maintenance test time clock can be reset for those components.

- PBM – Performance-Based Maintenance - intervals are established based on analytical or historical results of TBM failure rates on a statistically significant population of similar components. Some level of TBM is generally followed. Statistical analyses accompanied by adjustments to maintenance intervals are used to justify continued use of PBM-developed extended intervals when test failures or in-service failures occur infrequently.

- CBM – condition-based maintenance – continuously or frequently reported results from non-disruptive self-monitoring of components demonstrate operational status as those components remain in service. Whatever is verified by CBM does not require manual testing, but taking advantage of this requires precise technical focus on exactly what parts are included as part of the self-diagnostics. While the term "Condition-Based-Maintenance" (CBM) is no longer used within the standard itself, it is important to note that the concepts of CBM are a part of the standard (in the form of extended time intervals through status-monitoring). These extended time intervals are only allowed (in the absence of PBM) if the condition of the device is monitored (CBM). As a consequence of the "monitored-basis-time-intervals" existing within the standard, the explanatory

discussions within this Supplementary Reference concerned with CBM will remain in this reference and are discussed as CBM.

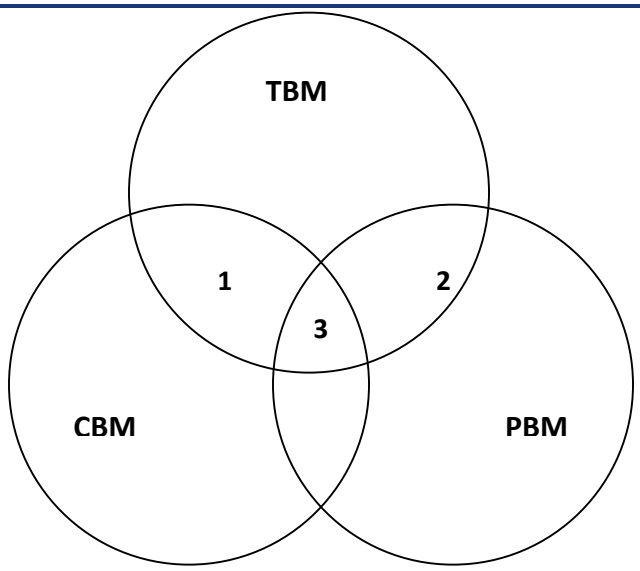
Microprocessor-based Protection System or Automatic Reclosing Components that perform continuous self-monitoring verify correct operation of most components within the device. Self-monitoring capabilities may include battery continuity, float voltages, unintentional grounds, the ac signal inputs to a relay, analog measuring circuits, processors and memory for measurement, protection, and data communications, trip circuit monitoring, and protection or data communications signals (and many, many more measurements). For those conditions, failure of a self-monitoring routine generates an alarm and may inhibit operation to avoid false trips. When internal components, such as critical output relay contacts, are not equipped with self-monitoring, they can be manually tested. The method of testing may be local or remote, or through inherent performance of the scheme during a system event.

The TBM is the overarching maintenance process of which the other types are subsets. Unlike TBM, PBM intervals are adjusted based on good or bad experiences. The CBM verification intervals can be hours, or even milliseconds between non-disruptive self-monitoring checks within or around components as they remain in service.

TBM, PBM, and CBM can be combined for individual components, or within a complete Protection System. The following diagram illustrates the relationship between various types of maintenance practices described in this section. In the Venn diagram, the overlapping regions show the relationship of TBM with PBM historical information and the inherent continuous monitoring offered through CBM.

This figure shows:

- Region 1: The TBM intervals that are increased based on known reported operational condition of individual components that are monitoring themselves.
- Region 2: The TBM intervals that are adjusted up or down based on results of analysis of maintenance history of statistically significant population of similar products that have been subject to TBM.
- Region 3: Optimal TBM intervals based on regions 1 and 2.



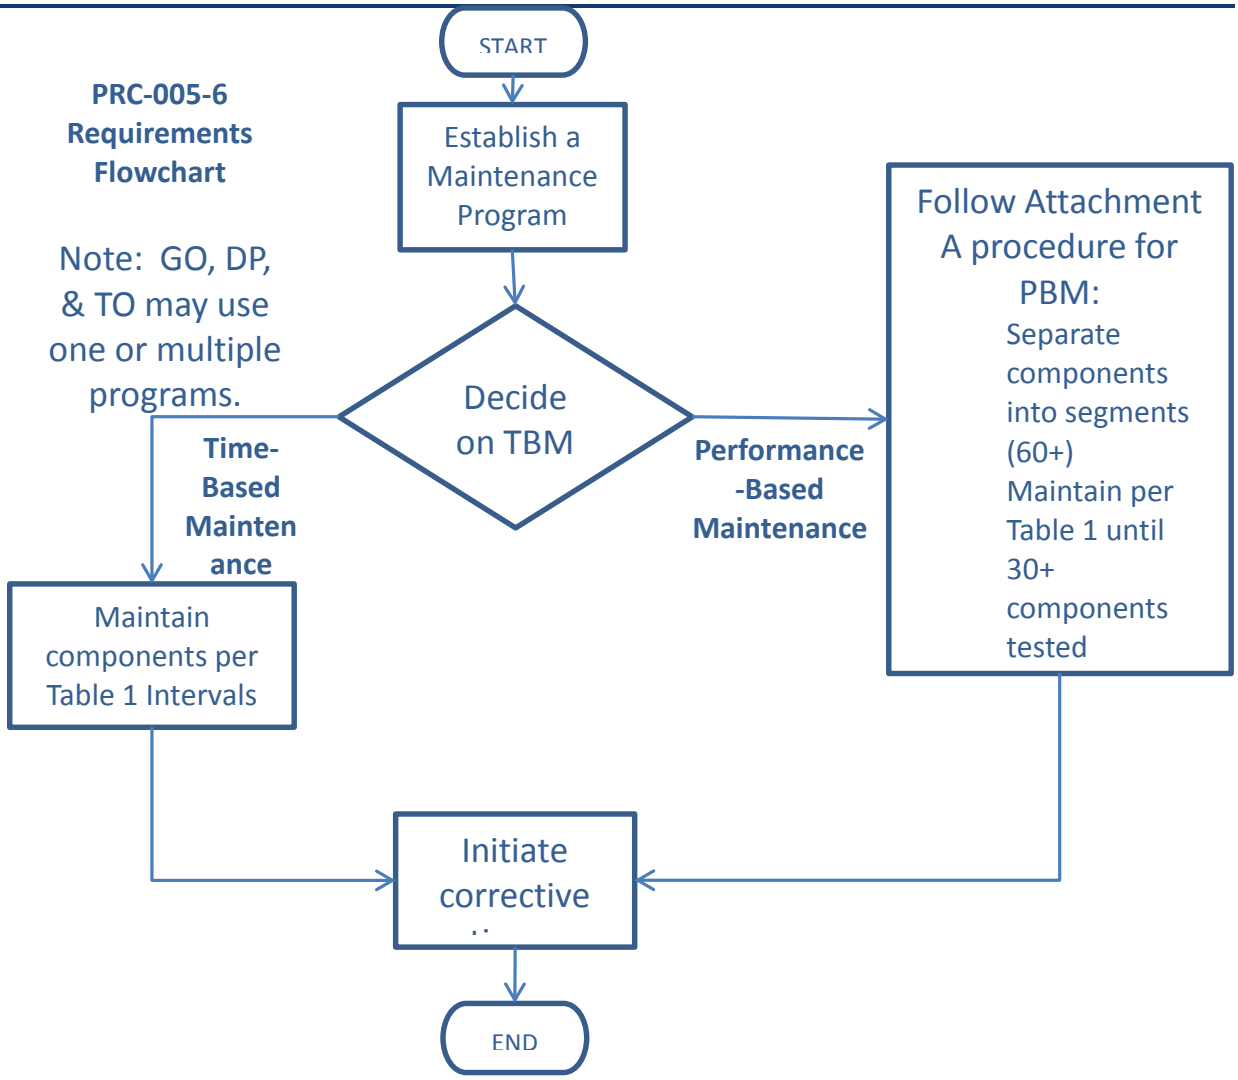
Relationship of time-based maintenance types

5.1.1 Frequently Asked Questions:

The standard seems very complicated, and is difficult to understand. Can it be simplified?

Because the standard is establishing parameters for condition-based Maintenance (R1) and Performance-Based Maintenance (R2), in addition to simple time-based Maintenance, it does appear to be complicated. At its simplest, an entity needs to ONLY perform time-based maintenance according to the unmonitored rows of the Tables. If an entity then wishes to take advantage of monitoring on its Protection System components and its available lengthened time intervals, then it may, as long as the component has the listed monitoring attributes. If an entity wishes to use historical performance of its Protection System components to perform Performance-Based Maintenance, then R2 applies.

Please see the following diagram, which provides a "flow chart" of the standard.



We have an electromechanical (unmonitored) relay that has a trip output to a lockout relay (unmonitored) which trips our transformer off-line by tripping the transformer's high-side and low-side circuit breakers. What testing must be done for this system?

This system is made up of components that are all unmonitored. Assuming a time-based Protection System Maintenance Program schedule (as opposed to a Performance-Based maintenance program), each component must be maintained per the most frequent hands-on activities listed in the Tables.

5.2 Extending Time-Based Maintenance

All maintenance is fundamentally time-based. Default time-based intervals are commonly established to assure proper functioning of each component of the Protection System, when data on the reliability of the components is not available other than observations from time-based maintenance. The following factors may influence the established default intervals:

- If continuous indication of the functional condition of a component is available (from relays or chargers or any self-monitoring device), then the intervals may be extended, or manual testing may be eliminated. This is referred to as condition-based maintenance or

CBM. CBM is valid only for precisely the components subject to monitoring. In the case of microprocessor-based relays, self-monitoring may not include automated diagnostics of every component within a microprocessor.

- Previous maintenance history for a group of components of a common type may indicate that the maintenance intervals can be extended, while still achieving the desired level of performance. This is referred to as Performance-Based Maintenance, or PBM. It is also sometimes referred to as reliability-centered maintenance, or RCM; but PBM is used in this document.
- Observed proper operation of a component may be regarded as a maintenance verification of the respective component or element in a microprocessor-based device. For such an observation, the maintenance interval may be reset only to the degree that can be verified by data available on the operation. For example, the trip of an electromechanical relay for a Fault verifies the trip contact and trip path, but only through the relays in series that actually operated; one operation of this relay cannot verify correct calibration.

Excessive maintenance can actually decrease the reliability of the component or system. It is not unusual to cause failure of a component by removing it from service and restoring it. The improper application of test signals may cause failure of a component. For example, in electromechanical overcurrent relays, test currents have been known to destroy convolution springs.

In addition, maintenance usually takes the component out of service, during which time it is not able to perform its function. Cutout switch failures, or failure to restore switch position, commonly lead to protection failures.

5.2.1 Frequently Asked Questions:

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) (in essence) state "…shall demonstrate efforts to correct identified Unresolved Maintenance Issues." The type of corrective activity is not stated; however it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity could very well ask for documentation showing status of your corrective actions.

6. Condition-Based Maintenance (CBM) Programs

Condition-based maintenance is the process of gathering and monitoring the information available from modern microprocessor-based relays and other intelligent electronic devices (IEDs) that monitor Protection System or Automatic Reclosing elements. These devices generate monitoring information during normal operation, and the information can be assessed at a convenient location remote from the substation. The information from these relays and IEDs is divided into two basic types:

1. Information can come from background self-monitoring processes, programmed by the manufacturer, or by the user in device logic settings. The results are presented by alarm contacts or points, front panel indications, and by data communications messages.
2. Information can come from event logs, captured files, and/or oscillographic records for Faults and Disturbances, metered values, and binary input status reports. Some of these are available on the device front panel display, but may be available via data communications ports. Large files of Fault information can only be retrieved via data communications. These results comprise a mass of data that must be further analyzed for evidence of the operational condition of the Protection System.

Using these two types of information, the user can develop an effective maintenance program carried out mostly from a central location remote from the substation. This approach offers the following advantages:

Non-invasive Maintenance: The system is kept in its normal operating state, without human intervention for checking. This reduces risk of damage, or risk of leaving the system in an inoperable state after a manual test. Experience has shown that keeping human hands away from equipment known to be working correctly enhances reliability.

Virtually Continuous Monitoring: CBM will report many hardware failure problems for repair within seconds or minutes of when they happen. This reduces the percentage of problems that are discovered through incorrect relaying performance. By contrast, a hardware failure discovered by TBM may have been there for much of the time interval between tests, and there is a good chance that some devices will show health problems by incorrect operation before being caught in the next test round. The frequent or continuous nature of CBM makes the effective verification interval far shorter than any required TBM maximum interval. To use the extended time intervals available through Condition Based Maintenance, simply look for the rows in the Tables that refer to monitored items.

6.1 Frequently Asked Questions:

My microprocessor relays and dc circuit alarms are contained on relay panels in a 24-hour attended control room. Does this qualify as an extended time interval condition-based (monitored) system?

Yes, provided the station attendant (plant operator, etc.) monitors the alarms and other indications (comparable to the monitoring attributes) and reports them within the given time limits that are stated in the criteria of the Tables.

When documenting the basis for inclusion of components into the appropriate levels of monitoring, as per Requirement R1 (Part 1.2) of the standard, is it necessary to provide this documentation about the device by listing of every component and the specific monitoring attributes of each device?

No. While maintaining this documentation on the device level would certainly be permissible, it is not necessary. Global statements can be made to document appropriate levels of monitoring for the entire population of a component type or portion thereof.

For example, it would be permissible to document the conclusion that all BES substation dc supply battery chargers are monitored by stating the following within the program description:

> "All substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center."

Similarly, it would be acceptable to use a combination of a global statement and a device-level list of exclusions. Example:

> "Except as noted below, all substation dc supply battery chargers are considered monitored and subject to the rows for monitored equipment of Table 1-4 requirements, as all substation dc supply battery chargers are equipped with dc voltage alarms and ground detection alarms that are sent to the manned control center. The dc supply battery chargers of Substation X, Substation Y, and Substation Z are considered unmonitored and subject to the rows for unmonitored equipment in Table 1-4 requirements, as they are not equipped with ground detection capability."

Regardless whether this documentation is provided by device listing of monitoring attributes, by global statements of the monitoring attributes of an entire population of component types, or by some combination of these methods, it should be noted that auditors may request supporting drawings or other documentation necessary to validate the inclusion of the device(s) within the appropriate level of monitoring. This supporting background information need not be maintained within the program document structure, but should be retrievable if requested by an auditor.

The applicability of R1.2 depends on the BES definition for Protection System to identify what components are to be covered by the Standard. One type of component is described as "Protective relays which respond to electrical quantities". Would a protection function that is embedded in a Generator's voltage regulator meet the BES defintion for Protection System and thus be included in R1.2?

Yes. The fact that these functions are implemented by an excitation system or voltage regulator rather than a classical looking relay is immaterial. The devices monitor electrical parameters such as voltage and/or current and cause a trip of the generator in response to these signals. By implementing these functions in the excitation system, the excitation system has in essence become an elaborate form of a microprocessor relay.

The voltage regulator processes electrical quantities and has an output that trips the generator breaker, quite often through a lockout. Examples include voltage regulator electronic cards that monitor voltage for high V/Hz, high exciter field voltage or both. In oldergeneration regulators (1980s and 1990s) the protection functions are essentially electronic relays (not

electromechanical or microprocessor based but using transistors and potentiometers). Should either excess voltage condition be true, a contact mounted on the voltage regulator electronics board closes which, in turn, goes to an auxiliary relay or activates a lockout relay directly. The electronic quantities monitored include exciter field voltage, generator current, and generator terminal voltage.

7. Time-Based Versus Condition-Based Maintenance

Time-based and condition-based (or monitored) maintenance programs are both acceptable, if implemented according to technically sound requirements. Practical programs can employ a *combination of time-based and condition-based maintenance.* The standard requirements introduce the concept of optionally using condition monitoring as a documented element of a maintenance program.

The Federal Energy Regulatory Commission (FERC), in its Order Number 693 Final Rule, dated March 16, 2007 (18 CFR Part 40, Docket No. RM06-16-000) on Mandatory Reliability Standards for the Bulk-Power System, directed NERC to submit a modification to PRC-005-1b that includes a requirement that maintenance and testing of a Protection System must be carried out within a maximum allowable interval that is appropriate to the type of the Protection System and its impact on the reliability of the Bulk Power System. Accordingly, this Supplementary Reference Paper refers to the specific maximum allowable intervals in PRC-005-4. The defined time limits allow for longer time intervals if the maintained component is monitored.

A key feature of condition-based monitoring is that it effectively reduces the time delay between the moment of a protection failure and time the Protection System or Automatic Reclosing owner knows about it, for the monitored segments of the Protection System. In some cases, the verification is practically continuous - the time interval between verifications is minutes or seconds. Thus, technically sound, condition-based verification, meets the verification requirements of the FERC order even more effectively than the strictly time-based tests of the same system components.

The result is that:

This NERC standard permits utilities to use a technically sound approach and to take advantage of remote monitoring, data analysis, and control capabilities of modern Protection System and Automatic Reclosing Components to reduce the need for periodic site visits and invasive testing of components by on-site technicians. This periodic testing must be conducted within the maximum time intervals specified in the Tables of PRC-005-4.

7.1 Frequently Asked Questions:

What is a Calendar Year?

Calendar Year - January 1 through December 31 of any year. As an example, if an event occurred on June 17, 2009 and is on a "One Calendar Year Interval," the next event would have to occur on or before December 31, 2010.

Please provide an example of "4 Calendar Months".

If a maintenance activity is described as being needed every four Calendar Months then it is performed in a (given) month and due again four months later. For example a battery bank is inspected in month number 1 then it is due again before the end of the month number5. And specifically consider that you perform your battery inspection on January 3, 2010 then it must be inspected again before the end of May. Another example could be that a four-month inspection was performed in January is due in May, but if performed in March (instead of May) would still

be due four months later therefore the activity is due again July. Basically every "four Calendar Months" means to add four months from the last time the activity was performed.

Please provide an example of the unmonitored versus other levels of monitoring available?

An unmonitored Protection System has no monitoring and alarm circuits on the Protection System components. A Protection System component that has monitoring attributes but no alarm output connected is considered to be unmonitored.

A monitored Protection System or an individual monitored component of a Protection System has monitoring and alarm circuits on the Protection System components. The alarm circuits must alert, within 24 hours, a location wherein corrective action can be initiated. This location might be, but is not limited to, an Operations Center, Dispatch Office, Maintenance Center or even a portable SCADA system.

There can be a combination of monitored and unmonitored Protection Systems within any given scheme, substation or plant; there can also be a combination of monitored and unmonitored components within any given Protection System.

Example #1: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with an internal alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self-diagnosis and alarming. (monitored)
- Instrumentation transformers, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented Lead-Acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, and the trip circuit is not monitored. (unmonitored)

Given the particular components and conditions, and using Table 1 and Table 2, the particular components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system).

Every 18 calendar months, verify/inspect the following:

- Battery bank ohmic values to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance

- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests or other measurements indicative of battery performance are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power System input values seen by the microprocessor protective relay
- Verify that current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- The microprocessor relay alarm signals are conveyed to a location where corrective action can be initiated
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained as detailed in Table 1-5 of the standard under the 'Unmonitored Control Circuitry Associated with Protective Functions" section'
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #2: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with integral alarm that is not connected to SCADA. (unmonitored)
- Current and voltage signal values, with no monitoring, connected as inputs to that relay. (unmonitored)
- A vented lead-acid battery with a low voltage alarm for the station dc supply voltage and an unintentional grounds detection alarm connected to SCADA. (monitoring varies)
- A circuit breaker with a trip coil, with no circuits monitored. (unmonitored)

Given the particular components and conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular components have maximum activity intervals of:

Every four calendar months, inspect:

- Electrolyte level (station dc supply voltage and unintentional ground detection is being maintained more frequently by the monitoring system)

Every 18 calendar months, verify/inspect the following:

- Battery bank trending of ohmic values or other measurements indicative of battery performance to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Cell condition of all individual battery cells (where visible)
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)

Every six calendar years, verify/perform the following:

- Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System
- Verify acceptable measurement of power system input values as seen by the relays
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip
- Battery performance test (if internal ohmic tests are not opted)

Every 12 calendar years, verify the following:

- Current and voltage signal values are provided to the protective relays
- Protection System component monitoring for the battery system signals are conveyed to a location where corrective action can be initiated
- All trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices
- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions" section
- Auxiliary outputs not in a trip path (i.e., annunciation or DME input) are not required, by this standard, to be checked

Example #3: A combination of monitored and unmonitored components within a given Protection System might be:

- A microprocessor relay with alarm connected to SCADA to alert 24-hr staffed operations center; it has internal self-diagnosis and alarms. (monitored)

- Current and voltage signal values, with monitoring, connected as inputs to that relay (monitored)
- Vented Lead-Acid battery without any alarms connected to SCADA (unmonitored)
- Circuit breaker with a trip coil, with no circuits monitored (unmonitored)

Given the particular components, conditions, and using the Table 1 (Maximum Allowable Testing Intervals and Maintenance Activities) and Table 2 (Alarming Paths and Monitoring), the particular components shall have maximum activity intervals of:

Every four calendar months, verify/inspect the following:

- Station dc supply voltage
- For unintentional grounds
- Electrolyte level

Every 18 calendar months, verify/inspect the following:

- Battery bank trending of ohmic values or other measurements indicative of battery performance to station battery baseline (if performance tests are not opted)
- Battery charger float voltage
- Battery rack integrity
- Battery continuity
- Battery terminal connection resistance
- Battery cell-to-cell resistance (where available to measure)
- Condition of all individual battery cells (where visible)

Every six calendar years, perform/verify the following:

- Battery performance test (if internal ohmic tests or other measurements indicative of battery performance are not opted)
- Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device
- For electromechanical lock-out relays, electrical operation of electromechanical trip

Every 12 calendar years, verify the following:

- The microprocessor relay alarm signals are conveyed to a location where corrective action can be taken
- Microprocessor relay settings are as specified
- Operation of the microprocessor's relay inputs and outputs that are essential to proper functioning of the Protection System
- Acceptable measurement of power system input values seen by the microprocessor protective relay
- Verify all trip paths in the control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

- Auxiliary outputs that are in the trip path shall be maintained, as detailed in Table 1-5 of the standard under the Unmonitored Control Circuitry Associated with Protective Functions section
- Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked

Why do components have different maintenance activities and intervals if they are monitored?

The intent behind different activities and intervals for monitored equipment is to allow less frequent manual intervention when more information is known about the condition of Protection System components. Condition-Based Maintenance is a valuable asset to improve reliability.

Can all components in a Protection System be monitored?

No. For some components in a Protection System, monitoring will not be relevant. For example, a battery will always need some kind of inspection.

We have a 30-year-old oil circuit breaker with a red indicating lamp on the substation relay panel that is illuminated only if there is continuity through the breaker trip coil. There is no SCADA monitor or relay monitor of this trip coil. The line protection relay package that trips this circuit breaker is a microprocessor relay that has an integral alarm relay that will assert on a number of conditions that includes a loss of power to the relay. This alarm contact connects to our SCADA system and alerts our 24-hour operations center of relay trouble when the alarm contact closes. This microprocessor relay trips the circuit breaker only and does not monitor trip coil continuity or other things such as trip current. Are the components monitored or not? How often must I perform maintenance?

The protective relay is monitored and can be maintained every 12 years, or when an Unresolved Maintenance Issue arises. The control circuitry can be maintained every 12 years. The circuit breaker trip coil(s) has to be electrically operated at least once every six years.

What is a mitigating device?

A mitigating device is the device that acts to respond as directed by a Remedial Action Schemes. It may be a breaker, valve, distributed control system, or any variety of other devices. This response may include tripping, closing, or other control actions.

8. Maximum Allowable Verification Intervals

The maximum allowable testing intervals and maintenance activities show how CBM with newer device types can reduce the need for many of the tests and site visits that older Protection System components require. As explained below, there are some sections of the Protection System that monitoring or data analysis may not verify. Verifying these sections of the Protection System or Automatic Reclosing requires some persistent TBM activity in the maintenance program. However, some of this TBM can be carried out remotely - for example, exercising a circuit breaker through the relay tripping circuits using the relay remote control capabilities can be used to verify function of one tripping path and proper trip coil operation, if there has been no Fault or routine operation to demonstrate performance of relay tripping circuits.

8.1 Maintenance Tests

Periodic maintenance testing is performed to ensure that the protection and control system is operating correctly after a time period of field installation. These tests may be used to ensure that individual components are still operating within acceptable performance parameters - this type of test is needed for components susceptible to degraded or changing characteristics due to aging and wear. Full system performance tests may be used to confirm that the total Protection System functions from measurement of power system values, to properly identifying Fault characteristics, to the operation of the interrupting devices.

8.1.1 Table of Maximum Allowable Verification Intervals

Table 1 (collectively known as Table 1, individually called out as Tables 1-1 through 1-5), Table 2, Table 3, Table 4-1 through Table 4-3, and Table 5 in the standard specify maximum allowable verification intervals for various generations of Protection Systems, Automatic Reclosing and Sudden Pressure Relaying and categories of equipment that comprise these systems. The right column indicates maintenance activities required for each category.

The types of components are illustrated in Figures 1 and 2 at the end of this paper. Figure 1 shows an example of telecommunications-assisted transmission Protection System comprising substation equipment at each terminal and a telecommunications channel for relaying between the two substations. Figure 2 shows an example of a generation Protection System. The various sub-systems of a Protection System that need to be verified are shown.

Non-distributed UFLS, UVLS, and RAS are additional categories of Table 1 that are not illustrated in these figures. Non-distributed UFLS, UVLS and RAS all use identical equipment as Protection Systems in the performance of their functions; and, therefore, have the same maintenance needs.

Distributed UFLS and UVLS Systems, which use local sensing on the distribution System and trip co-located non-BES interrupting devices, are addressed in Table 3 with reduced maintenance activities.

While it is easy to associate protective relays to multiple levels of monitoring, it is also true that most of the components that can make up a Protection System can also have technological advancements that place them into higher levels of monitoring.

To use the Maintenance Activities and Intervals Tables from PRC-005-4:

- First find the Table associated with your component. The tables are arranged in the order of mention in the definition of Protection System;
    - Table 1-1 is for protective relays,
    - Table 1-2 is for the associated communications systems,
    - Table 1-3 is for current and voltage sensing devices,
    - Table 1-4 is for station dc supply and
    - Table 1-5 is for control circuits.
    - Table 2, is for alarms; this was broken out to simplify the other tables.
    - Table 3 is for components which make-up distributed UFLS and UVLS Systems.
    - Table 4 is for Automatic Reclosing.
    - Table 5 is for Sudden Pressure Relaying.
- Next look within that table for your device and its degree of monitoring. The Tables have different hands-on maintenance activities prescribed depending upon the degree to which you monitor your equipment. Find the maintenance activity that applies to the monitoring level that you have on your piece of equipment.
- This Maintenance activity is the minimum maintenance activity that must be documented.
- If your Performance-Based Maintenance (PBM) plan requires more activities, then you must perform and document to this higher standard. (Note that this does not apply unless you utilize PBM.)
- After the maintenance activity is known, check the maximum maintenance interval; this time is the maximum time allowed between hands-on maintenance activity cycles of this component.
- If your Performance-Based Maintenance plan requires activities more often than the Tables maximum, then you must perform and document those activities to your more stringent standard. (Note that this does not apply unless you utilize PBM.)
- Any given component of a Protection System can be determined to have a degree of monitoring that may be different from another component within that same Protection System. For example, in a given Protection System it is possible for an entity to have a monitored protective relay and an unmonitored associated communications system; this combination would require hands-on maintenance activity on the relay at least once every 12 years and attention paid to the communications system as often as every four months.
- An entity does not have to utilize the extended time intervals made available by this use of condition-based monitoring. An easy choice to make is to simply utilize the unmonitored level of maintenance made available in each of the Tables. While the maintenance activities resulting from this choice would require more maintenance man-

hours, the maintenance requirements may be simpler to document and the resulting maintenance plans may be easier to create.

For each Protection System Component, Table 1 shows maximum allowable testing intervals for the various degrees of monitoring. For each Automatic Reclosing Component, Table 4 shows maximum allowable testing intervals for the various degrees of monitoring. These degrees of monitoring, or levels, range from the legacy unmonitored through a system that is more comprehensively monitored.

It has been noted here that an entity may have a PSMP that is more stringent than PRC-005-4. There may be any number of reasons that an entity chooses a more stringent plan than the minimums prescribed within PRC-005-4, most notable of which is an entity using performance based maintenance methodology.

If an entity has a Performance-Based Maintenance program, then that plan must be followed, even if the plan proves to be more stringent than the minimums laid out in the Tables.

If an entity has a Time-Based Maintenance program and the PSMP is more stringent than PRC-005-4, they will only be audited in accordance with the standard (minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3, and Table 5).

8.1.2 Additional Notes for Tables 1-1 through 1-5, Table 3, and Table 4

1. For electromechanical relays, adjustment is required to bring measurement accuracy within the tolerance needed by the asset owner. Microprocessor relays with no remote monitoring of alarm contacts, etc., are unmonitored relays and need to be verified within the Table interval as other unmonitored relays but may be verified as functional by means other than testing by simulated inputs.

2. Microprocessor relays typically are specified by manufacturers as not requiring calibration, but acceptable measurement of power system input values must be verified (verification of the Analog to Digital [A/D] converters) within the Table intervals. The integrity of the digital inputs and outputs that are used as protective functions must be verified within the Table intervals.

3. Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or RAS (as opposed to a monitoring task) must be verified as a component in a Protection System.

4. In addition to verifying the circuitry that supplies dc to the Protection System, the owner must maintain the station dc supply. The most widespread station dc supply is the station battery and charger. Unlike most Protection System components, physical inspection of station batteries for signs of component failure, reduced performance, and degradation are required to ensure that the station battery is reliable enough to deliver dc power when required. IEEE Standards 450, 1188, and 1106 for vented lead-acid, valve-regulated lead-acid, and nickel-cadmium batteries, respectively (which are the most commonly used substation batteries on the NERC BES) have been developed as an important reference source of maintenance recommendations. The Protection System owner might want to follow the guidelines in the applicable IEEE recommended practices for battery maintenance and testing, especially if the battery in question is used for application requirements in addition to the protection and control demands covered under this

standard. However, the Standard Drafting Team has tailored the battery maintenance and testing guidelines in PRC-005-4 for the Protection System owner which are application specific for the BES Facilities. While the IEEE recommendations are all encompassing, PRC-005-4 is a more economical approach while addressing the reliability requirements of the BES.

5. Aggregated small entities might distribute the testing of the population of UFLS/UVLS systems, and large entities will usually maintain a portion of these systems in any given year. Additionally, if relatively small quantities of such systems do not perform properly, it will not affect the integrity of the overall program. Thus, these distributed systems have decreased requirements as compared to other Protection Systems.

6. Voltage & current sensing device circuit input connections to the Protection System relays can be verified by (but not limited to) comparison of measured values on live circuits or by using test currents and voltages on equipment out of service for maintenance. The verification process can be automated or manual. The values should be verified to be as expected (phase value and phase relationships are both equally important to verify).

7. "End-to-end test," as used in this Supplementary Reference, is any testing procedure that creates a remote input to the local communications-assisted trip scheme. While this can be interpreted as a GPS-type functional test, it is not limited to testing via GPS. Any remote scheme manipulation that can cause action at the local trip path can be used to functionally-test the dc control circuitry. A documented Real-time trip of any given trip path is acceptable in lieu of a functional trip test. It is possible, with sufficient monitoring, to be able to verify each and every parallel trip path that participated in any given dc control circuit trip. Or another possible solution is that a single trip path from a single monitored relay can be verified to be the trip path that successfully tripped during a Real-time operation. The variations are only limited by the degree of engineering and monitoring that an entity desires to pursue.

8. A/D verification may use relay front panel value displays, or values gathered via data communications. Groupings of other measurements (such as vector summation of bus feeder currents) can be used for comparison if calibration requirements assure acceptable measurement of power system input values.

9. Notes 1-8 attempt to describe some testing activities; they do not represent the only methods to achieve these activities, but rather some possible methods. Technological advances, ingenuity and/or industry accepted techniques can all be used to satisfy maintenance activity requirements; the standard is technology- and method-neutral in most cases.

8.1.3 Frequently Asked Questions:

What is meant by "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed mostly towards microprocessor- based relays. For relay maintenance departments that choose to test microprocessor-based relays in the same manner as electromechanical relays are tested, the testing process sometimes requires that some specific functions be disabled. Later tests might enable the functions previously

disabled, but perhaps still other functions or logic statements were then masked out. It is imperative that, when the relay is placed into service, the settings in the relay be the settings that were intended to be in that relay or as the standard states "…settings are as specified."

Many of the microprocessor- based relays available today have software tools which provide this functionality and generate reports for this purpose.

For evidence or documentation of this requirement, a simple recorded acknowledgement that the settings were checked to be as specified is sufficient.

The drafting team was careful not to require "…that the relay settings be correct…" because it was believed that this might then place a burden of proof that the specified settings would result in the correct intended operation of the interrupting device. While that is a noble intention, the measurable proof of such a requirement is immense. The intent is that settings of the component be as specified at the conclusion of maintenance activities, whether those settings may have "drifted" since the prior maintenance or whether changes were made as part of the testing process.

Are electromechanical relays included in the "Verify that settings are as specified" maintenance activity in Table 1-1?

Verification of settings is an activity directed towards the application of protection related functions of microprocessor based relays. Electromechanical relays require calibration verification by voltage and/or current injection; and, thus, the settings are verified during calibration activity. In the example of a time-overcurrent relay, a minor deviation in time dial, versus the settings, may be acceptable, as long as the relay calibration is within accepted tolerances at the injected current amplitudes. A major deviation may require further investigation, as it could indicate a problem with the relay or an incorrect relay style for the application.

The verification of phase current and voltage measurements by comparison to other quantities seems reasonable. How, though, can I verify residual or neutral currents, or 3V0 voltages, by comparison, when my system is closely balanced?

Since these inputs are verified at commissioning, maintenance verification requires ensuring that phase quantities are as expected and that 3IO and 3VO quantities appear equal to or close to 0.

These quantities also may be verified by use of oscillographic records for connected microprocessor relays as recorded during system Disturbances. Such records may compare to similar values recorded at other locations by other microprocessor relays for the same event, or compared to expected values (from short circuit studies) for known Fault locations.

What does this Standard require for testing an auxiliary tripping relay?

Table 1 and Table 3 requires that a trip test must verify that the auxiliary tripping relay(s) and/or lockout relay(s) which are directly in a trip path from the protective relay to the interrupting device trip coil operate(s) electrically. Auxiliary outputs not in a trip path (i.e. annunciation or DME input) are not required, by this standard, to be checked.

Do I have to perform a full end-to-end test of a Remedial Action Schemes?

No. All portions of the -RAS need to be maintained, and the portions must overlap, but the overall RAS does not need to have a single end-to-end test. In other words it may be tested in piecemeal fashion provided all of the pieces are verified.

What about RAS interfaces between different entities or owners?

As in all of the Protection System requirements, RAS segments can be tested individually, thus minimizing the need to accommodate complex maintenance schedules.

What do I have to do if I am using a phasor measurement unit (PMU) as part of a Protection System or Remedial Action Schemes?

Any Phasor Measurement Unit (PMU) function whose output is used in a Protection System or Remedial Action Schemes (as opposed to a monitoring task) must be verified as a component in a Protection System.

How do I maintain a Remedial Action Schemes or relay sensing for non-distributed UFLS or UVLS Systems?

Since components of the RAS, UFLS and UVLS are the same types of components as those in Protection Systems, then these components should be maintained like similar components used for other Protection System functions. In many cases the devices for RAS, UFLS and UVLS are also used for other protective functions. The same maintenance activities apply with the exception that distributed systems (UFLS and UVLS) have fewer dc supply and control circuitry maintenance activity requirements.

For the testing of the output action, verification may be by breaker tripping, but may be verified in overlapping segments. For example, an RAS that trips a remote circuit breaker might be tested by testing the various parts of the scheme in overlapping segments. Another method is to document the Real-time tripping of an RAS scheme should that occur. Forced trip tests of circuit breakers (etc.) that are a part of distributed UFLS or UVLS schemes are not required.

The established maximum allowable intervals do not align well with the scheduled outages for my power plant. Can I extend the maintenance to the next scheduled outage following the established maximum interval?

No. You must complete your maintenance within the established maximum allowable intervals in order to be compliant. You will need to schedule your maintenance during available outages to complete your maintenance as required, even if it means that you may do protective relay maintenance more frequently than the maximum allowable intervals. The maintenance intervals were selected with typical plant outages, among other things, in mind.

If I am unable to complete the maintenance, as required, due to a major natural disaster (hurricane, earthquake, etc.), how will this affect my compliance with this standard?

The Sanction Guidelines of the North American Electric Reliability Corporation, effective January 15, 2008, provides that the Compliance Monitor will consider extenuating circumstances when considering any sanctions.

What if my observed testing results show a high incidence of out-of-tolerance relays; or, even worse, I am experiencing numerous relay Misoperations due to the relays being out-of-tolerance?

The established maximum time intervals are mandatory only as a not-to-exceed limitation. The establishment of a maximum is measurable. But any entity can choose to test some or all of their Protection System components more frequently (or to express it differently, exceed the minimum requirements of the standard). Particularly if you find that the maximum intervals in the standard do not achieve your expected level of performance, it is understandable that you would maintain the related equipment more frequently. A high incidence of relay Misoperations is in no one's best interest.

We believe that the four-month interval between inspections is unneccessary. Why can we not perform these inspections twice per year?

The Standard Drafting Team, through the comment process, has discovered that routine monthly inspections are not the norm. To align routine station inspections with other important inspections, the four-month interval was chosen. In lieu of station visits, many activities can be accomplished with automated monitoring and alarming.

Our maintenance plan calls for us to perform routine protective relay tests every 3 years. If we are unable to achieve this schedule, but we are able to complete the procedures in less than the maximum time interval ,then are we in or out of compliance?

According to R3, if you have a time-based maintenance program, then you will be in violation of the standard only if you exceed the maximum maintenance intervals prescribed in the Tables. According to R4, if your device in question is part of a Performance-Based Maintenance program, then you will be in violation of the standard if you fail to meet your PSMP, even if you do not exceed the maximum maintenance intervals prescribed in the Tables. The intervals in the Tables are associated with TBM and CBM; Attachment A is associated with PBM.

Please provide a sample list of devices or systems that must be verified in a generator, generator step-up transformer, generator connected station service or generator connected excitation transformer to meet the requirements of this maintenance standard.

Examples of typical devices and systems that may directly trip the generator, or trip through a lockout relay, may include, but are not necessarily limited to:

- Fault protective functions, including distance functions, voltage-restrained overcurrent functions, or voltage-controlled overcurrent functions
- Loss-of-field relays
- Volts-per-hertz relays
- Negative sequence overcurrent relays
- Over voltage and under voltage protection relays
- Stator-ground relays
- Communications-based Protection Systems such as transfer-trip systems
- Generator differential relays
- Reverse power relays
- Frequency relays

- Out-of-step relays
- Inadvertent energization protection
- Breaker failure protection

For generator step-up, generator-connected station service transformers, or generator connected excitation transformers, operation of any of the following associated protective relays frequently would result in a trip of the generating unit; and, as such, would be included in the program:

- Transformer differential relays
- Neutral overcurrent relay
- Phase overcurrent relays

Relays which trip breakers serving station auxiliary Loads such as pumps, fans, or fuel handling equipment, etc., need not be included in the program, even if the loss of the those Loads could result in a trip of the generating unit. Furthermore, relays which provide protection to secondary unit substation (SUS) or low switchgear transformers and relays protecting other downstream plant electrical distribution system components are not included in the scope of this program, even if a trip of these devices might eventually result in a trip of the generating unit. For example, a thermal overcurrent trip on the motor of a coal-conveyor belt could eventually lead to the tripping of the generator, but it does not cause the trip.

In the case where a plant does not have a generator connected station service transformer such that it is normally fed from a system connected station service transformer, is it still the drafting team's intent to exclude the Protection Systems for these system connected auxiliary transformers from scope even when the loss of the normal (system connected) station service transformer will result in a trip of a BES generating Facility?

The SDT does not intend that the system-connected station service transformers be included in the Applicability. The generator-connected station service transformers and generator connected excitation transformers are often connected to the generator bus directly without an interposing breaker; thus, the Protection Systems on these transformers will trip the generator as discussed in 4.2.5.1.

What is meant by "verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System?"

Any input or output (of the relay) that "affects the tripping" of the breaker is included in the scope of I/O of the relay to be verified. By "affects the tripping," one needs to realize that sometimes there are more inputs and outputs than simply the output to the trip coil. Many important protective functions include things like breaker fail initiation, zone timer initiation and sometimes even 52a/b contact inputs are needed for a protective relay to correctly operate.

Each input should be "picked up" or "turned on and off" and verified as changing state by the microprocessor of the relay. Each output should be "operated" or "closed and opened" from the microprocessor of the relay and the output should be verified to change state on the output

terminals of the relay. One possible method of testing inputs of these relays is to "jumper" the needed dc voltage to the input and verify that the relay registered the change of state.

Electromechanical lock-out relays (86) (used to convey the tripping current to the trip coils) need to be electrically operated to prove the capability of the device to change state. These tests need to be accomplished at least every six years, unless PBM methodology is applied.

The contacts on the 86 or auxiliary tripping relays (94) that change state to pass on the trip current to a breaker trip coil need only be checked every 12 years with the control circuitry.

What is the difference between a distributed UFLS/UVLS and a non-distributed UFLS/UVLS scheme?

A distributed UFLS or UVLS scheme contains individual relays which make independent Load shed decisions based on applied settings and localized voltage and/or current inputs. A distributed scheme may involve an enable/disable contact in the scheme and still be considered a distributed scheme. A non-distributed UFLS or UVLS scheme involves a system where there is some type of centralized measurement and Load shed decision being made. A non-distributed UFLS/UVLS scheme is considered similar to an RAS scheme and falls under Table 1 for maintenance activities and intervals.

8.2 Retention of Records

PRC-005-1 describes a reporting or auditing cycle of one year and retention of records for three years. However, with a three-year retention cycle, the records of verification for a Protection System might be discarded before the next verification, leaving no record of what was done if a Misoperation or failure is to be analyzed.

PRC-005-4 corrects this by requiring:

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated Protection System Maintenance Program, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component Type.

For Requirement R2, Requirement R3, and Requirement R4, in cases where the interval of the maintenance activity is longer than the audit cycle, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performance of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component. In cases where the interval of the maintenance activity is shorter than the audit cycle, documentation of all performances (in accordance with the tables) of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component since the previous scheduled audit date shall be retained.

For Requirement R5 the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of Unresolved Maintenance Issues identified by the entity since the last audit, including all that were resolved since the last audit.

This requirement assures that the documentation shows that the interval between maintenance cycles correctly meets the maintenance interval limits. The requirement is actually alerting the industry to documentation requirements already implemented by audit teams. Evidence of compliance bookending the interval shows interval accomplished instead of proving only your planned interval.

The SDT is aware that, in some cases, the retention period could be relatively long. But, the retention of documents simply helps to demonstrate compliance.

8.2.1 Frequently Asked Questions:

Please clarify the data retention requirements.

The data retention requirements are intended to allow the availability of maintenance records to demonstrate that the time intervals in your maintenance plan were upheld.

Maximum Maintenance Interval	**Data Retention Period**
4 Months, 6 Months,18 Months, or 3 Years	All activities since previous audit
6 Years	All activities since previous audit(assuming a 6 year audit cycle) or most recent performance(assuming 3 year audit cycle), whichever is longer
12 Year	All activities from the most recent performance

If an entity prefers to utilize Performance-Based Maintenance, then statistical data may well be retained for extended periods to assist with future adjustments in time intervals.

If an equipment item is replaced, then the entity can restart the maintenance-time-interval-clock if desired; however, the replacement of equipment does not remove any documentation requirements that would have been required to verify compliance with time-interval requirements. In other words, do not discard maintenance data that goes to verify your work.

The retention of documentation for new and/or replaced equipment is all about proving that the maintenance intervals had been in compliance. For example, a long-range plan of upgrades might lead an entity to ignore required maintenance; retaining the evidence of prior maintenance that existed before any retirements and upgrades proves compliance with the standard.

What does this Maintenance Standard say about commissioning? Is it necessary to have documentation in your maintenance history of the completion of commission testing?

This standard does not establish requirements for commission testing. Commission testing includes all testing activities necessary to conclude that a Facility has been built in accordance with design. While a thorough commission testing program would include, either directly or indirectly, the verification of all those Protection System attributes addressed by the

maintenance activities specified in the Tables of PRC-005-4, verification of the adequacy of initial installation necessitates the performance of testing and inspections that go well beyond these routine maintenance activities. For example, commission testing might set baselines for future tests; perform acceptance tests and/or warranty tests; utilize testing methods that are not generally done routinely like staged-Fault-tests.

However, many of the Protection System attributes which are verified during commission testing are not subject to age related or service related degradation, and need not be re-verified within an ongoing maintenance program. Example – it is not necessary to re-verify correct terminal strip wiring on an ongoing basis.

PRC-005-4 assumes that thorough commission testing was performed prior to a Protection System being placed in service. PRC-005-4 requires performance of maintenance activities that are deemed necessary to detect and correct plausible age and service related degradation of components, such that a properly built and commission tested Protection System will continue to function as designed over its service life.

It should be noted that commission testing frequently is performed by a different organization than that which is responsible for the ongoing maintenance of the Protection System. Furthermore, the commission testing activities will not necessarily correlate directly with the maintenance activities required by the standard. As such, it is very likely that commission testing records will deviate significantly from maintenance records in both form and content; and, therefore, it is not necessary to maintain commission testing records within the maintenance program documentation.

Notwithstanding the differences in records, an entity would be wise to retain commissioning records to show a maintenance start date. (See below). An entity that requires that their commissioning tests have, at a minimum, the requirements of PRC-005-4 would help that entity prove time interval maximums by setting the initial time clock.

How do you determine the initial due date for maintenance?

The initial due date for maintenance should be based upon when a Protection System was tested. Alternatively, an entity may choose to use the date of completion of the commission testing of the Protection System component and the system was placed into service as the starting point in determining its first maintenance due dates. Whichever method is chosen, for newly installed Protection Systems the components should not be placed into service until minimum maintenance activities have taken place.

It is conceivable that there can be a (substantial) difference in time between the date of testing, as compared to the date placed into service. The use of the "Calendar Year" language can help determine the next due date without too much concern about being non-compliant for missing test dates by a small amount (provided your dates are not already at the end of a year). However, if there is a substantial amount of time difference between testing and in-service dates, then the testing date should be followed because it is the degradation of components that is the concern. While accuracy fluctuations may decrease when components are not energized, there are cases when degradation can take place, even though the device is not energized. Minimizing the time between commissioning tests and in-service dates will help.

If I miss two battery inspections four times out of 100 Protection System components on my transmission system, does that count as 2% or 8% when counting Violation Severity Level (VSL) for R3?

The entity failed to complete its scheduled program on two of its 100 Protection System components, which would equate to 2% for application to the VSL Table for Requirement R3. This VSL is written to compare missed components to total components. In this case two components out of 100 were missed, or 2%.

How do I achieve a "grace period" without being out of compliance?

The objective here is to create a time extension within your own PSMP that still does not violate the maximum time intervals stated in the standard. Remember that the maximum time intervals listed in the Tables cannot be extended.

For the purposes of this example, concentrating on just unmonitored protective relays – Table 1-1 specifies a maximum time interval (between the mandated maintenance activities) of six calendar years. Your plan must ensure that your unmonitored relays are tested at least once every six calendar years. You could, within your PSMP, require that your unmonitored relays be tested every four calendar years, with a maximum allowable time extension of 18 calendar months. This allows an entity to have deadlines set for the auto-generation of work orders, but still has the flexibility in scheduling complex work schedules. This also allows for that 18 calendar months to act as a buffer, in effect a grace period within your PSMP, in the event of unforeseen events. You will note that this example of a maintenance plan interval has a planned time of four years; it also has a built-in time extension allowed within the PSMP, and yet does not exceed the maximum time interval allowed by the standard. So while there are no time extensions allowed beyond the standard, an entity can still have substantial flexibility to maintain their Protection System components.

8.3 Basis for Table 1 Intervals

When developing the original *Protection System Maintenance – A Technical Reference* in 2007, the SPCTF collected all available data from Regional Entities (REs) on time intervals recommended for maintenance and test programs. The recommendations vary widely in categorization of relays, defined maintenance actions, and time intervals, precluding development of intervals by averaging. The SPCTF also reviewed the 2005 Report [2] of the IEEE Power System Relaying Committee Working Group I-17 (Transmission Relay System Performance Comparison). Review of the I-17 report shows data from a small number of utilities, with no company identification or means of investigating the significance of particular results.

To develop a solid current base of practice, the SPCTF surveyed its members regarding their maintenance intervals for electromechanical and microprocessor relays, and asked the members to also provide definitively-known data for other entities. The survey represented 470 GW of peak Load, or 4% of the NERC peak Load. Maintenance interval averages were compiled by weighting reported intervals according to the size (based on peak Load) of the reporting utility. Thus, the averages more accurately represent practices for the large populations of Protection Systems used across the NERC regions.

The results of this survey with weighted averaging indicate maintenance intervals of five years for electromechanical or solid state relays, and seven years for unmonitored microprocessor relays.

A number of utilities have extended maintenance intervals for microprocessor relays beyond seven years, based on favorable experience with the particular products they have installed. To

provide a technical basis for such extension, the SPCTF authors developed a recommendation of 10 years using the Markov modeling approach from [1], as summarized in Section 8.4. The results of this modeling depend on the completeness of self-testing or monitoring. Accordingly, this extended interval is allowed by Table 1, only when such relays are monitored as specified in the attributes of monitoring contained in Tables 1-1 through 1-5 and Table 2. Monitoring is capable of reporting Protection System health issues that are likely to affect performance within the 10 year time interval between verifications.

It is important to note that, according to modeling results, Protection System availability barely changes as the maintenance interval is varied below the 10-year mark. Thus, reducing the maintenance interval does not improve Protection System availability. With the assumptions of the model regarding how maintenance is carried out, reducing the maintenance interval actually degrades Protection System availability.

8.4 Basis for Extended Maintenance Intervals for Microprocessor Relays

Table 1 allows maximum verification intervals that are extended based on monitoring level. The industry has experience with self-monitoring microprocessor relays that leads to the Table 1 value for a monitored relay, as explained in Section 8.3. To develop a basis for the maximum interval for monitored relays in their *Protection System Maintenance – A Technical Reference*, the SPCTF used the methodology of Reference [1], which specifically addresses optimum routine maintenance intervals. The Markov modeling approach of [1] is judged to be valid for the design and typical failure modes of microprocessor relays.

The SPCTF authors ran test cases of the Markov model to calculate two key probability measures:

- Relay Unavailability - the probability that the relay is out of service due to failure or maintenance activity while the power system Element to be protected is in service.
- Abnormal Unavailability - the probability that the relay is out of service due to failure or maintenance activity when a Fault occurs, leading to failure to operate for the Fault.

The parameter in the Markov model that defines self-monitoring capability is ST (for self-test). ST = 0 if there is no self-monitoring; ST = 1 for full monitoring. Practical ST values are estimated to range from .75 to .95. The SPCTF simulation runs used constants in the Markov model that were the same as those used in [1] with the following exceptions:

Sn, Normal tripping operations per hour = 21600 (reciprocal of normal Fault clearing time of 10 cycles)

Sb, Backup tripping operations per hour = 4320 (reciprocal of backup Fault clearing time of 50 cycles)

Rc, Protected component repairs per hour = 0.125 (8 hours to restore the power system)

Rt, Relay routine tests per hour = 0.125 (8 hours to test a Protection System)

Rr, Relay repairs per hour = 0.08333 (12 hours to complete a Protection System repair after failure)

Experimental runs of the model showed low sensitivity of optimum maintenance interval to these parameter adjustments.

The resulting curves for relay unavailability and abnormal unavailability versus maintenance interval showed a broad minimum (optimum maintenance interval) in the vicinity of 10 years –

the curve is flat, with no significant change in either unavailability value over the range of 9, 10, or 11 years. This was true even for a relay mean time between Failures (MTBF) of 50 years, much lower than MTBF values typically published for these relays. Also, the Markov modeling indicates that both the relay unavailability and abnormal unavailability actually become higher with more frequent testing. This shows that the time spent on these more frequent tests yields no failure discoveries that approach the negative impact of removing the relays from service and running the tests.

The PSMT SDT discussed the practical need for "time-interval extensions" or "grace periods" to allow for scheduling problems that resulted from any number of business contingencies. The time interval discussions also focused on the need to reflect industry norms surrounding Generator outage frequencies. Finally, it was again noted that FERC Order 693 demanded maximum time intervals. "Maximum time intervals" by their very term negates any "time-interval extension" or "grace periods." To recognize the need to follow industry norms on Generator outage frequencies and accommodate a form of time-interval extension, while still following FERC Order 693, the Standard Drafting Team arrived at a six-year interval for the electromechanical relay, instead of the five-year interval arrived at by the SPCTF. The PSMT SDT has followed the FERC directive for a *maximum* time interval and has determined that no extensions will be allowed. Six years has been set for the maximum time interval between manual maintenance activities. This maximum time interval also works well for maintenance cycles that have been in use in generator plants for decades.

For monitored relays, the PSMT SDT notes that the SPCTF called for 10 years as the interval between maintenance activities. This 10-year interval was chosen, even though there was "…no significant change in unavailability value over the range of 9, 10, or 11 years. This was true even for a relay Mean Time between Failures (MTBF) of 50 years…" The Standard Drafting Team again sought to align maintenance activities with known successful practices and outage schedules. The Standard does not allow extensions on any component of the Protection System; thus, the maximum allowed interval for these components has been set to 12 years. Twelve years also fits well into the traditional maintenance cycles of both substations and generator plants.

Also of note is the Table's use of the term "Calendar" in the column for "Maximum Maintenance Interval." The PSMT SDT deemed it necessary to include the term "Calendar" to facilitate annual maintenance planning, scheduling and implementation. This need is the result of known occurrences of system requirements that could cause maintenance schedules to be missed by a few days or weeks. The PSMT SDT chose the term "Calendar" to preclude the need to have schedules be met to the day. An electromechanical protective relay that is maintained in year number one need not be revisited until six years later (year number seven). For example, a relay was maintained April 10, 2008; maintenance would need to be completed no later than December 31, 2014.

Though not a requirement of this standard, to stay in line with many Compliance Enforcement Agencies audit processes an entity should define, within their own PSMP, the entity's use of terms like annual, calendar year, etc. Then, once this is within the PSMP, the entity should abide by their chosen language.

9. Performance-Based Maintenance Process

In lieu of using the Table 1 intervals, a Performance-Based Maintenance process may be used to establish maintenance intervals (*PRC-005 Attachment A Criteria for a Performance-Based Protection System Maintenance Program*). A Performance-Based Maintenance process may justify longer maintenance intervals, or require shorter intervals relative to Table 1. In order to use a Performance-Based Maintenance process, the documented maintenance program must include records of repairs, adjustments, and corrections to covered Protection Systems in order to provide historical justification for intervals, other than those established in Table 1. Furthermore, the asset owner must regularly analyze these records of corrective actions to develop a ranking of causes. Recurrent problems are to be highlighted, and remedial action plans are to be documented to mitigate or eliminate recurrent problems.

Entities with Performance-Based Maintenance track performance of Protection Systems, demonstrate how they analyze findings of performance failures and aberrations, and implement continuous improvement actions. Since no maintenance program can ever guarantee that no malfunction can possibly occur, documentation of a Performance-Based Maintenance program would serve the utility well in explaining to regulators and the public a Misoperation leading to a major System outage event.

A Performance-Based Maintenance program requires auditing processes like those included in widely used industrial quality systems (such as ***ISO 9001-2000, Quality Management Systems — Requirements;*** or applicable parts of the NIST Baldridge National Quality Program). The audits periodically evaluate:

- The completeness of the documented maintenance process
- Organizational knowledge of and adherence to the process
- Performance metrics and documentation of results
- Remediation of issues
- Demonstration of continuous improvement.

In order to opt into a Performance-Based Maintenance (PBM) program, the asset owner must first sort the various Components into population segments. Any population segment must be comprised of at least 60 individual units; if any asset owner opts for PBM, but does not own 60 units to comprise a population, then that asset owner may combine data from other asset owners until the needed 60 units is aggregated. Each population segment must be composed of a grouping of Components of a consistent design standard or particular model or type from a single manufacturer and subjected to similar environmental factors. For example: One segment cannot be comprised of both GE & Westinghouse electro-mechanical lock-out relays; likewise, one segment cannot be comprised of 60 GE lock-out relays, 30 of which are in a dirty environment, and the remaining 30 from a clean environment. This PBM process cannot be applied to batteries, but can be applied to all other Components, including (but not limited to) specific battery chargers, instrument transformers, trip coils and/or control circuitry (etc.).

9.1 Minimum Sample Size

Large Sample Size

An assumption that needs to be made when choosing a sample size is "the sampling distribution of the sample mean can be approximated by a normal probability distribution." The Central Limit Theorem states: "In selecting simple random samples of size *n* from a population, the sampling distribution of the sample mean *x* can be approximated by a normal probability distribution as the sample size becomes large." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)

To use the Central Limit Theorem in statistics, the population size should be large. The references below are supplied to help define what is large.

> "… whenever we are using a large simple random sample (rule of thumb: n>=30), the central limit theorem enables us to conclude that the sampling distribution of the sample mean can be approximated by a normal distribution." (Essentials of Statistics for Business and Economics, Anderson, Sweeney, Williams, 2003.)
>
> "If samples of size n, when n>=30, are drawn from any population with a mean *u* and a standard deviation σ, the sampling distribution of sample means approximates a normal distribution. The greater the sample size, the better the approximation." (Elementary Statistics - Picturing the World, Larson, Farber, 2003.)
>
> "The sample size is large (generally n>=30)… (Introduction to Statistics and Data Analysis - Second Edition, Peck, Olson, Devore, 2005.)
>
> "… the normal is often used as an approximation to the *t* distribution in a test of a null hypothesis about the mean of a normally distributed population when the population variance is estimated from a relatively large sample. A sample size exceeding 30 is often given as a minimal size in this connection." (Statistical Analysis for Business Decisions, Peters, Summers, 1968.)

Error of Distribution Formula

Beyond the large sample size discussion above, a sample size requirement can be estimated using the bound on the Error of Distribution Formula when the expected result is of a "Pass/Fail" format and will be between 0 and 1.0.

The Error of Distribution Formula is:

$$B = z\sqrt{\frac{\pi(1-\pi)}{n}}$$

Where:

B = bound on the error of distribution (allowable error)

z = standard error

π = expected failure rate

n = sample size required

Solving for n provides:

$$n = \pi(1-\pi)\left(\frac{z}{B}\right)^2$$

Minimum Population Size to use Performance-Based Program

One entity's population of components should be large enough to represent a sizeable sample of a vendor's overall population of manufactured devices. For this reason, the following assumptions are made:

B = 5%

z = 1.96 (This equates to a 95% confidence level)

π = 4%

Using the equation above, n=59.0.

Minimum Sample Size to evaluate Performance-Based Program

The number of components that should be included in a sample size for evaluation of the appropriate testing interval can be smaller because a lower confidence level is acceptable since the sample testing is repeated or updated annually. For this reason, the following assumptions are made:

B = 5%

z = 1.44 (85% confidence level)

π = 4%

Using the equation above, n=31.8.

Recommendation

Based on the above discussion, a sample size should be at least 30 to allow use of the equation mentioned. Using this and the results of the equation, the following numbers are recommended (and required within the standard):

Minimum Population Size to use Performance-Based Maintenance Program = 60

Minimum Sample Size to evaluate Performance-Based Program = 30.

Once the population segment is defined, then maintenance must begin within the intervals as outlined for the device described in the Tables 1-1 through 1-5. Time intervals can be lengthened provided the last year's worth of components tested (or the last 30 units maintained, whichever is more) had fewer than 4% Countable Events. It is notable that 4% is specifically chosen because an entity with a small population (30 units) would have to adjust its time intervals between maintenance if more than one Countable Event was found to have occurred during the last analysis period. A smaller percentage would require that entity to adjust the time interval between maintenance activities if even one unit is found out of tolerance or causes a Misoperation.

The minimum number of units that can be tested in any given year is 5% of the population. Note that this 5% threshold sets a practical limitation on total length of time between intervals at 20 years.

If at any time the number of Countable Events equals or exceeds 4% of the last year's tested components (or the last 30 units maintained, whichever is more), then the time period between manual maintenance activities must be decreased. There is a time limit on reaching the decreased time at which the Countable Events is less than 4%; this must be attained within three years.

Performance-Based Program Evaluation Example

The 4% performance target was derived as a protection system performance target and was selected based on the drafting team's experience and studies performed by several utilities. This is not derived from the performance of discrete devices. Microprocessor relays and electromechanical relays have different performance levels. It is not appropriate to compare these performance levels to each other. The performance of the segment should be compared to the 4% performance criteria.

In consideration of the use of Performance Based Maintenance (PBM), the user should consider the effects of extended testing intervals and the established 4% failure rate. In the table shown below, the segment is 1000 units. As the testing interval (in years) increases, the number of units tested each year decreases. The number of countable events allowed is 4% of the tested units. Countable events are the failure of a Component requiring repair or replacement, any corrective actions performed during the maintenance test on the units within the testing segment (units per year), or any misoperation attributable to hardware failure or calibration failure found within the entire segment (1000 units) during the testing year.

Example: 1000 units in the segment with a testing interval of 8 years: The number of units tested each year will be 125 units. The total allowable countable events equals: 125 X .04 = 5. This number includes failure of a Component requiring repair or replacement, corrective issues found during testing, and the total number of misoperations (attributable to hardware or calibration failure within the testing year) associated with the entire segment of 1000 units.

Example: 1000 units in the segment with a testing interval of 16 years: The number of units tested each year will be 63 units. The total allowable countable events equals: 63 X .04 = 2.5.

As shown in the above examples, doubling the testing interval reduces the number of allowable events by half.

Total number of units in the segment	1000
Failure rate	4.00%

Testing Intervals (Years)	Units Per Year	Acceptable Number of Countable Events per year	Yearly Failure Rate Based on 1000 Units in Segment
1	1000.00	40.00	4.00%
2	500.00	20.00	2.00%
4	250.00	10.00	1.00%
6	166.67	6.67	0.67%
8	125.00	5.00	0.50%
10	100.00	4.00	0.40%
12	83.33	3.33	0.33%
14	71.43	2.86	0.29%
16	62.50	2.50	0.25%
18	55.56	2.22	0.22%
20	50.00	2.00	0.20%

Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

Segment – Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual Components.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5, Table 3, Table 4-1 through Table 4-3, and Table 5, which requires corrective action or a Protection System Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component, Automatic Reclosing, or Sudden Pressure Relaying configuration or application errors are not included in Countable Events.

9.2 Frequently Asked Questions:

I'm a small entity and cannot aggregate a population of Protection System components to establish a segment required for a Performance-Based Protection System Maintenance Program. How can I utilize that opportunity?

Multiple asset owning entities may aggregate their individually owned populations of individual Protection System components to create a segment that crosses ownership boundaries. All entities participating in a joint program should have a single documented joint management process, with consistent Protection System Maintenance Programs (practices, maintenance

intervals and criteria), for which the multiple owners are individually responsible with respect to the requirements of the Standard. The requirements established for Performance-Based Maintenance must be met for the overall aggregated program on an ongoing basis.

The aggregated population should reflect all factors that affect consistent performance across the population, including any relevant environmental factors such as geography, power-plant vs. substation, and weather conditions.

Can an owner go straight to a Performance-Based Maintenance program schedule, if they have previously gathered records?

Yes. An owner can go to a Performance-Based Maintenance program immediately. The owner will need to comply with the requirements of a Performance-Based Maintenance program as listed in the Standard. Gaps in the data collected will not be allowed; therefore, if an owner finds that a gap exists such that they cannot prove that they have collected the data as required for a Performance-Based Maintenance program then they will need to wait until they can prove compliance.

When establishing a Performance-Based Maintenance program, can I use test data from the device manufacturer, or industry survey results, as results to help establish a basis for my Performance-Based intervals?

No, you must use actual in-service test data for the components in the segment.

What types of Misoperations or events are not considered Countable Events in the Performance-Based Protection System Maintenance (PBM) Program?

Countable Events are intended to address conditions that are attributed to hardware failure or calibration failure; that is, conditions that reflect deteriorating performance of the component. These conditions include any condition where the device previously worked properly, then, due to changes within the device, malfunctioned or degraded to the point that re-calibration (to within the entity's tolerance) was required.

For this purpose of tracking hardware issues, human errors resulting in Protection System Misoperations during system installation or maintenance activities are not considered Countable Events. Examples of excluded human errors include relay setting errors, design errors, wiring errors, inadvertent tripping of devices during testing or installation, and misapplication of Protection System components. Examples of misapplication of Protection System components include wrong CT or PT tap position, protective relay function misapplication, and components not specified correctly for their installation. Obviously, if one is setting up relevant data about hardware failures then human failures should be eliminated from the hardware performance analysis.

One example of human-error is not pertinent data might be in the area of testing "86" lock-out relays (LOR). "Entity A" has two types of LOR's type "X" and type "Y"; they want to move into a performance based maintenance interval. They have 1000 of each type, so the population variables are met. During electrical trip testing of all of their various schemes over the initial six-year interval they find zero type "X" failures, but human error led to tripping a BES Element 100 times; they find 100 type "Y" failures and had an additional 100 human-error caused tripping incidents. In this example the human-error caused Misoperations should not be used to judge the performance of either type of LOR. Analysis of the data might lead "Entity A" to change time intervals. Type "X" LOR can be placed into extended time interval testing because of its low failure

rate (zero failures) while Type "Y" would have to be tested more often than every 6 calendar years (100 failures divided by 1000 units exceeds the 4% tolerance level).

Certain types of Protection System component errors that cause Misoperations are not considered Countable Events. Examples of excluded component errors include device malfunctions that are correctable by firmware upgrades and design errors that do not impact protection function.

What are some examples of methods of correcting segment perfomance for Performance-Based Maintenance?

There are a number of methods that may be useful for correcting segment performance for mal-performing segments in a Performance-Based Maintenance system. Some examples are listed below.

- The maximum allowable interval, as established by the Performance-Based Maintenance system, can be decreased. This may, however, be slow to correct the performance of the segment.
- Identifiable sub-groups of components within the established segment, which have been identified to be the mal-performing portion of the segment, can be broken out as an independent segment for target action. Each resulting segment must satisfy the minimum population requirements for a Performance-Based Maintenance program in order to remain within the program.
- Targeted corrective actions can be taken to correct frequently occurring problems. An example would be replacement of capacitors within electromechanical distance relays if bad capacitors were determined to be the cause of the mal-performance.
- components within the mal-performing segment can be replaced with other components (electromechanical distance relays with microprocessor relays, for example) to remove the mal-performing segment.

If I find (and correct) a Unresolved Maintenance Issue as a result of a Misoperation investigation (Re: PRC-004), how does this affect my Performance-Based Maintenance program?

If you perform maintenance on a Protection System component for any reason (including as part of a PRC-004 required Misoperation investigation/corrective action), the actions performed can count as a maintenance activity provided the activities in the relevant Tables have been done, and, if you desire, "reset the clock" on everything you've done. In a Performance-Based Maintenance program, you also need to record the Unresolved Maintenance Issue as a Countable Event within the relevant component group segment and use it in the analysis to determine your correct Performance-Based Maintenance interval for that component group. Note that "resetting the clock" should not be construed as interfering with an entity's routine testing schedule because the "clock-reset" would actually make for a decreased time interval by the time the next routine test schedule comes around.

For example a relay scheme, consisting of four relays, is tested on 1-1-11 and the PSMP has a time interval of 3 calendar years with an allowable extension of 1 calendar year. The relay would be due again for routine testing before the end of the year 2015. This mythical relay scheme has a Misoperation on 6-1-12 that points to one of the four relays as bad. Investigation proves a bad relay and a new one is tested and installed in place of the original. This replacement relay actually

could be retested before the end of the year 2016 (clock-reset) and not be out of compliance. This requires tracking maintenance by individual relays and is allowed. However, many companies schedule maintenance in other ways like by substation or by circuit breaker or by relay scheme. By these methods of tracking maintenance that "replaced relay" will be retested before the end of the year 2015. This is also acceptable. In no case was a particular relay tested beyond the PSMP of four years max, nor was the 6 year max of the Standard exceeded. The entity can reset the clock if they desire or the entity can continue with original schedules and, in effect, test even more frequently.

Why are batteries excluded from PBM? What about exclusion of batteries from condition based maintenance?

Batteries are the only element of a Protection System that is a perishable item with a shelf life. As a perishable item batteries require not only a constant float charge to maintain their freshness (charge), but periodic inspection to determine if there are problems associated with their aging process and testing to see if they are maintaining a charge or can still deliver their rated output as required.

Besides being perishable, a second unique feature of a battery that is unlike any other Protection System element is that a battery uses chemicals, metal alloys, plastics, welds, and bonds that must interact with each other to produce the constant dc source required for Protection Systems, undisturbed by ac system Disturbances.

No type of battery manufactured today for Protection System application is free from problems that can only be detected over time by inspection and test. These problems can arise from variances in the manufacturing process, chemicals and alloys used in the construction of the individual cells, quality of welds and bonds to connect the components, the plastics used to make batteries and the cell forming process for the individual battery cells.

Other problems that require periodic inspection and testing can result from transportation from the factory to the job site, length of time before a charge is put on the battery, the method of installation, the voltage level and duration of equalize charges, the float voltage level used, and the environment that the battery is installed in.

All of the above mentioned factors and several more not discussed here are beyond the control of the Functional Entities that want to use a Performance-Based Protection System Maintenance (PBM) program. These inherent variances in the aging process of a battery cell make establishment of a designated segment based on manufacturer and type of battery impossible.

The whole point of PBM is that if all variables are isolated then common aging and performance criteria would be the same. However, there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria.

Similarly, Functional Entities that want to establish a condition-based maintenance program using the highest levels of monitoring, resulting in the least amount of hands-on maintenance activity, cannot completely eliminate some periodic maintenance of the battery used in a station dc supply. Inspection of the battery is required on a Maximum Maintenance Interval listed in the tables due to the aging processes of station batteries. However, higher degrees of

monitoring of a battery can eliminate the requirement for some periodic testing and some inspections (see Table 1-4).

Please provide an example of the calculations involved in extending maintenance time intervals using PBM.

Entity has 1000 GE-HEA lock-out relays; this is greater than the minimum sample requirement of 60. They start out testing all of the relays within the prescribed Table requirements (6 year max) by testing the relays every 5 years. The entity's plan is to test 200 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only the following will show 6 failures per year, reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests the entity finds 6 failures in the 200 units tested. 6/200= 3% failure rate. This entity is now allowed to extend the maintenance interval if they choose. The entity chooses to extend the maintenance interval of this population segment out to 10 years. This represents a rate of 100 units tested per year; entity selects 100 units to be tested in the following year. After that year of testing these 100 units the entity again finds 6 failed units. 6/100= 6% failures. This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year). In response to the 6% failure rate, the entity decreases the testing interval to 8 years. This means that they will now test 125 units per year (1000/8). The entity has just two years left to get the test rate corrected.

After a year, they again find six failures out of the 125 units tested. 6/125= 5% failures. In response to the 5% failure rate, the entity decreases the testing interval to seven years. This means that they will now test 143 units per year (1000/7). The entity has just one year left to get the test rate corrected. After a year, they again find six failures out of the 143 units tested. 6/143= 4.2% failures.

(Note that the entity has tried five years and they were under the 4% limit and they tried seven years and they were over the 4% limit. They must be back at 4% failures or less in the next year so they might simply elect to go back to five years.)

Instead, in response to the 5% failure rate, the entity decreases the testing interval to six years. This means that they will now test 167 units per year (1000/6). After a year, they again find six failures out of the 167 units tested. 6/167= 3.6% failures. Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at six years or less. Entity chose six-year interval and effectively extended their TBM (five years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20 year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	5 yrs	200	6	3%	Yes	10 yrs
2	1000	10 yrs	100	6	6%	Yes	8 yrs
3	1000	8 yrs	125	6	5%	Yes	7 yrs
4	1000	7 yrs	143	6	4.2%	Yes	6 yrs
5	1000	6 yrs	167	6	3.6%	No	6 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for control circuitry.

Note that the following example captures "Control Circuitry" as all of the trip paths associated with a particular trip coil of a circuit breaker. An entity is not restricted to this method of counting control circuits. Perhaps another method an entity would prefer would be to simply track every individual (parallel) trip path. Or perhaps another method would be to track all of the trip outputs from a specific (set) of relays protecting a specific element.

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment –*Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 1,000 circuit breakers, all of which have two trip coils, for a total of 2,000 trip coils; if all circuitry was designed and built with a consistent (internal entity) standard, then this is greater than the minimum sample requirement of 60.

For the sake of further example, the following facts are given:

Half of all relay panels (500) were built 40 years ago by an outside contractor, consisted of asbestos wrapped 600V-insulation panel wiring, and the cables exiting the control house are THHN pulled in conduit direct to exactly half of all of the various circuit breakers. All of the relay panels and cable pulls were built with consistent standards and consistent performance standard expectations within the segment (which is greater than 60). Each relay panel has redundant microprocessor (MPC) relays (retrofitted); each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker.

Approximately 35 years ago, the entity developed their own internal construction crew and now builds all of their own relay panels from parts supplied from vendors that meet the entity's specifications, including SIS 600V insulation wiring and copper-sheathed cabling within the direct conduits to circuit breakers. The construction crew uses consistent standards in the construction. This newer segment of their control circuitry population is different than the original segment, consistent (standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population (another 500 panels and the cabling to the remaining 500 circuit breakers). Each relay panel has redundant microprocessor (MPC) relays; each MPC relay supplies an individual trip output to each of the two trip coils of the assigned circuit breaker. Every trip path in this newer segment has a device that monitors the voltage directly across the trip contacts of the MPC relays and alarms via RTU and SCADA to the

operations control room. This monitoring device, when not in alarm, demonstrates continuity all the way through the trip coil, cabling and wiring back to the trip contacts of the MPC relay.

The entity is tracking 2,000 trip coils (each consisting of multiple trip paths) in each of these two segments. But half of all of the trip paths are monitored; therefore, the trip paths are continuously tested and the circuit will alarm when there is a failure. These alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 trip coils (and associated trip paths) remaining that they have elected to count as control circuits. The entity has instituted a process that requires the verification of every trip path to each trip coil (one unit), including the electrical activation of the trip coil. (The entity notes that the trip coils will have to be tripped electrically more often than the trip path verification, and is taking care of this activity through other documentation of Real-time Fault operations.)

They start out testing all of the trip coil circuits within the prescribed Table requirements (12-year max) by testing the trip circuits every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4% failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the 4% limit; and they tried 14 years, and they were over the 4% limit. They must be back at 4% failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval, and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested / year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chosen
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

Please provide an example of the calculations involved in extending maintenance time intervals using PBM for voltage and current sensing devices.

Note that the following example captures "voltage and current inputs to the protective relays" as all of the various current transformer and potential transformer signals associated with a particular set of relays used for protection of a specific Element. This entity calls this set of protective relays a "Relay Scheme." Thus, this entity chooses to count PT and CT signals as a group instead of individually tracking maintenance activities to specific bushing CT's or specific PT's. An entity is not restricted to this method of counting voltage and current devices, signals and paths. Perhaps another method an entity would prefer would be to simply track every individual PT and CT. Note that a generation maintenance group may well select the latter because they may elect to perform routine off-line tests during generator outages, whereas a transmission maintenance group might create a process that utilizes Real-time system values measured at the relays.

The designation of what constitutes a control circuit component is very dependent upon how an entity performs and tracks the testing of the control circuitry. Some entities test their control circuits on a breaker basis whereas others test their circuitry on a local zone of protection basis. Thus, entities are allowed the latitude to designate their own definitions of control circuit components. Another example of where the entity has some discretion on determining what constitutes a single component is the voltage and current sensing devices, where the entity may choose either to designate a full three-phase set of such devices or a single device as a single component.

And in Attachment A (PBM) the definition of Segment:

Segment –*Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a segment. A segment must contain at least sixty (60) individual components.*

Example:

Entity has 2000 "Relay Schemes," all of which have three current signals supplied from bushing CTs, and three voltage signals supplied from substation bus PT's. All cabling and circuitry was designed and built with a consistent (internal entity) standard, and this population is greater than the minimum sample requirement of 60.

For the sake of further example the following facts are given:

Half of all relay schemes (1,000) are supplied with current signals from ANSI STD C800 bushing CTs and voltage signals from PTs built by ACME Electric MFR CO. All of the relay panels and cable pulls were built with consistent standards, and consistent performance standard expectations exist for the consistent wiring, cabling and instrument transformers within the segment (which is greater than 60).

The other half of the entity's relay schemes have MPC relays with additional monitoring built-in that compare DNP values of voltages and currents (or Watts and VARs), as interpreted by the MPC relays and alarm for an entity-accepted tolerance level of accuracy. This newer segment of their "Voltage and Current Sensing" population is different than the original segment, consistent

(standards, construction and performance expectations) within the new segment and constitutes the remainder of the entity's population.

The entity is tracking many thousands of voltage and current signals within 2,000 relay schemes (each consisting of multiple voltage and current signals) in each of these two segments. But half of all of the relay schemes voltage and current signals are monitored; therefore, the voltage and current signals are continuously tested and the circuit will alarm when there is a failure; these alarms have to be verified every 12 years for correct operation.

The entity now has 1,000 relay schemes worth of voltage and current signals remaining that they have elected to count within their relay schemes designation. The entity has instituted a process that requires the verification of these voltage and current signals within each relay scheme (one unit).

(Please note - a problem discovered with a current or voltage signal found at the relay could be caused by anything from the relay, all the way to the signal source itself. Having many sources of problems can easily increase failure rates beyond the rate of failures of just one item (for example just PTs). It is the intent of the SDT to minimize failure rates of all of the equipment to an acceptable level; thus, any failure of any item that gets the signal from source to relay is counted. It is for this reason that the SDT chose to set the boundary at the ability of the signal to be delivered all the way to the relay.

The entity will start out measuring all of the relay scheme voltage and currents at the individual relays within the prescribed Table requirements (12 year max) by measuring the voltage and current values every 10 years. The entity's plan is to test 100 units per year; this is greater than the minimum sample size requirement of 30. For the sake of example only, the following will show three failures per year; reality may well have different numbers of failures every year. PBM requires annual assessment of failures found per units tested. After the first year of tests, the entity finds three failures in the 100 units tested. 3/100= 3% failure rate.

This entity is now allowed to extend the maintenance interval, if they choose. The entity chooses to extend the maintenance interval of this population segment out to 20 years. This represents a rate of 50 units tested per year; entity selects 50 units to be tested in the following year. After that year of testing these 50 units, the entity again finds three failed units. 3/50= 6% failures.

This entity has now exceeded the acceptable failure rate for these devices and must accelerate testing of all of the units at a higher rate, such that the failure rate is found to be less than 4% per year; the entity has three years to get this failure rate down to 4% or less (per year).

In response to the 6% failure rate, the entity decreases the testing interval to 16 years. This means that they will now test 63 units per year (1000/16). The entity has just two years left to get the test rate corrected. After a year, they again find three failures out of the 63 units tested. 3/63= 4.76% failures.

In response to the >4%failure rate, the entity decreases the testing interval to 14 years. This means that they will now test 72 units per year (1000/14). The entity has just one year left to get the test rate corrected. After a year, they again find three failures out of the 72 units tested. 3/72= 4.2% failures.

(Note that the entity has tried 10 years, and they were under the 4% limit; and they tried 14 years, and they were over the 4% limit. They must be back at 4% failures or less in the next year, so they might simply elect to go back to 10 years.)

Instead, in response to the 4.2% failure rate, the entity decreases the testing interval to 12 years. This means that they will now test 84 units per year (1,000/12). After a year, they again find three failures out of the 84 units tested. 3/84= 3.6% failures.

Entity found that they could maintain the failure rate at no more than 4% failures by maintaining the testing interval at 12 years or less. Entity chose 12-year interval and effectively extended their TBM (10 years) program by 20%.

A note of practicality is that an entity will probably be in better shape to lengthen the intervals between tests if the failure rate is less than 2%. But the requirements allow for annual adjustments, if the entity desires. As a matter of maintenance management, an ever-changing test rate (units tested/year) may be un-workable.

Note that the "5% of components" requirement effectively sets a practical limit of 20-year maximum PBM interval. Also of note is the "3 years" requirement; an entity might arbitrarily extend time intervals from six years to 20 years. In the event that an entity finds a failure rate greater than 4%, then the test rate must be accelerated such that within three years the failure rate must be brought back down to 4% or less.

Here is a table that demonstrates the values discussed:

Year #	Total Population (P)	Test Interval (I)	Units to be Tested (U= P/I)	# of Failures Found (F)	Failure Rate (=F/U)	Decision to Change Interval Yes or No	Interval Chose
1	1000	10 yrs	100	3	3%	Yes	20 yrs
2	1000	20 yrs	50	3	6%	Yes	16yrs
3	1000	16 yrs	63	3	4.8%	Yes	14 yrs
4	1000	14 yrs	72	3	4.2%	Yes	12 yrs
5	1000	12 yrs	84	3	3.6%	No	12 yrs

10. Overlapping the Verification of Sections of the Protection System

Tables 1-1 through 1-5 require that every Protection System component be periodically verified. One approach, but not the only method, is to test the entire protection scheme as a unit, from the secondary windings of voltage and current sources to breaker tripping. For practical ongoing verification, sections of the Protection System may be tested or monitored individually. The boundaries of the verified sections must overlap to ensure that there are no gaps in the verification. See Appendix A of this Supplementary Reference for additional discussion on this topic.

All of the methodologies expressed within this report may be combined by an entity, as appropriate, to establish and operate a maintenance program. For example, a Protection System may be divided into multiple overlapping sections with a different maintenance methodology for each section:

- Time-based maintenance with appropriate maximum verification intervals for categories of equipment, as given in the Tables 1-1 through 1-5;
- Monitoring as described in Tables 1-1 through 1-5;
- A Performance-Based Maintenance program as described in Section 9 above, or Attachment A of the standard;
- Opportunistic verification using analysis of Fault records, as described in Section 11

10.1 Frequently Asked Questions:

My system has alarms that are gathered once daily through an auto-polling system; this is not really a conventional SCADA system but does it meet the Table 1 requirements for inclusion as a monitored system?

Yes, provided the auto-polling that gathers the alarms reports those alarms to a location where the action can be initiated to correct the Unresolved Maintenance Issue. This location does not have to be the location of the engineer or the technician that will eventually repair the problem, but rather a location where the action can be initiated.

11. Monitoring by Analysis of Fault Records

Many users of microprocessor relays retrieve Fault event records and oscillographic records by data communications after a Fault. They analyze the data closely if there has been an apparent Misoperation, as NERC standards require. Some advanced users have commissioned automatic Fault record processing systems that gather and archive the data. They search for evidence of component failures or setting problems hidden behind an operation whose overall outcome seems to be correct. The relay data may be augmented with independently captured Digital Fault Recorder (DFR) data retrieved for the same event.

Fault data analysis comprises a legitimate CBM program that is capable of reducing the need for a manual time-interval based check on Protection Systems whose operations are analyzed. Even electromechanical Protection Systems instrumented with DFR channels may achieve some CBM benefit. The completeness of the verification then depends on the number and variety of Faults in the vicinity of the relay that produce relay response records and the specific data captured.

A typical Fault record will verify particular parts of certain Protection Systems in the vicinity of the Fault. For a given Protection System installation, it may or may not be possible to gather within a reasonable amount of time an ensemble of internal and external Fault records that completely verify the Protection System.

For example, Fault records may verify that the particular relays that tripped are able to trip via the control circuit path that was specifically used to clear that Fault. A relay or DFR record may indicate correct operation of the protection communications channel. Furthermore, other nearby Protection Systems may verify that they restrain from tripping for a Fault just outside their respective zones of protection. The ensemble of internal Fault and nearby external Fault event data can verify major portions of the Protection System, and reset the time clock for the Table 1 testing intervals for the verified components only.

What can be shown from the records of one operation is very specific and limited. In a panel with multiple relays, only the specific relay(s) whose operation can be observed without ambiguity should be used. Be careful about using Fault response data to verify that settings or calibration are correct. Unless records have been captured for multiple Faults close to either side of a setting boundary, setting or calibration could still be incorrect.

PMU data, much like DME data, can be utilized to prove various components of the Protection System. Obviously, care must be taken to attribute proof only to the parts of a Protection System that can actually be proven using the PMU or DME data.

If Fault record data is used to show that portions or all of a Protection System have been verified to meet Table 1 requirements, the owner must retain the Fault records used, and the maintenance-related conclusions drawn from this data and used to defer Table 1 tests, for at least the retention time interval given in Section 8.2.

11.1 Frequently Asked Questions:

I use my protective relays for Fault and Disturbance recording, collecting oscillographic records and event records via communications for Fault analysis to meet NERC and DME requirements. What are the maintenance requirements for the relays?

For relays used only as Disturbance Monitoring Equipment, NERC Standard PRC-018-1 R3 & R6 states the maintenance requirements and is being addressed by a standards activity that is revising PRC-002-1 and PRC-018-1. For protective relays "that are designed to provide protection for the BES," this standard applies, even if they also perform DME functions.

12. Importance of Relay Settings in Maintenance Programs

In manual testing programs, many utilities depend on pickup value or zone boundary tests to show that the relays have correct settings and calibration. Microprocessor relays, by contrast, provide the means for continuously monitoring measurement accuracy. Furthermore, the relay digitizes inputs from one set of signals to perform all measurement functions in a single self-monitoring microprocessor system. These relays do not require testing or calibration of each setting.

However, incorrect settings may be a bigger risk with microprocessor relays than with older relays. Some microprocessor relays have hundreds or thousands of settings, many of which are critical to Protection System performance.

Monitoring does not check measuring element settings. Analysis of Fault records may or may not reveal setting problems. To minimize risk of setting errors after commissioning, the user should enforce strict settings data base management, with reconfirmation (manual or automatic) that the installed settings are correct whenever maintenance activity might have changed them; for background and guidance, see [5] in References.

Table 1 requires that settings must be verified to be as specified. The reason for this requirement is simple: With legacy relays (non-microprocessor protective relays), it is necessary to know the value of the intended setting in order to test, adjust and calibrate the relay. Proving that the relay works per specified setting was the de facto procedure. However, with the advanced microprocessor relays, it is possible to change relay settings for the purpose of verifying specific functions and then neglect to return the settings to the specified values. While there is no specific requirement to maintain a settings management process, there remains a need to verify that the settings left in the relay are the intended, specified settings. This need may manifest itself after any of the following:

- One or more settings are changed for any reason.
- A relay fails and is repaired or replaced with another unit.
- A relay is upgraded with a new firmware version.

12.1 Frequently Asked Questions:

How do I approach testing when I have to upgrade firmware of a microprocessor relay?

The entity should ensure that the relay continues to function properly after implementation of firmware changes. Some entities may have a R&D department that might routinely run acceptance tests on devices with firmware upgrades before allowing the upgrade to be installed. Other entities may rely upon the vigorous testing of the firmware OEM. An entity has the latitude to install devices and/or programming that they believe will perform to their satisfaction. If an entity should choose to perform the maintenance activities specified in the Tables following a firmware upgrade, then they may, if they choose, reset the time clock on that set of maintenance activities so that they would not have to repeat the maintenance on its regularly scheduled cycle.

(However, for simplicity in maintenance schedules, some entities may choose to not reset this time clock; it is merely a suggested option.)

If I upgrade my old relays, then do I have to maintain my previous equipment maintenance documentation?

If an equipment item is repaired or replaced, then the entity can restart the maintenance-activity-time-interval-clock, if desired; however, the replacement of equipment does not remove any documentation requirements. The requirements in the standard are intended to ensure that an entity has a maintenance plan, and that the entity adheres to minimum activities and maximum time intervals. The documentation requirements are intended to help an entity demonstrate compliance. For example, saving the dates and records of the last two maintenance activities is intended to demonstrate compliance with the interval. Therefore, if you upgrade or replace equipment, then you still must maintain the documentation for the previous equipment, thus demonstrating compliance with the time interval requirement prior to the replacement action.

We have a number of installations where we have changed our Protection System components. Some of the changes were upgrades, but others were simply system rating changes that merely required taking relays "out-of-service". What are our responsibilities when it comes to "out-of-service" devices?

Assuming that your system up-rates, upgrades and overall changes meet any and all other requirements and standards, then the requirements of PRC-005-4 are simple – if the Protection System component performs a Protection System function, then it must be maintained. If the component no longer performs Protection System functions, then it does not require maintenance activities under the Tables of PRC-005-4. While many entities might physically remove a component that is no longer needed, there is no requirement in PRC-005-4 to remove such component(s). Obviously, prudence would dictate that an "out-of-service" device is truly made inactive. There are no record requirements listed in PRC-005-4 for Protection System components not used.

While performing relay testing of a protective device on our Bulk Electric System, it was discovered that the protective device being tested was either broken or out of calibration. Does this satisfy the relay testing requirement, even though the protective device tested bad, and may be unable to be placed back into service?

Yes, PRC-005-4 requires entities to perform relay testing on protective devices on a given maintenance cycle interval. By performing this testing, the entity has satisfied PRC-005-4 requirement, although the protective device may be unable to be returned to service under normal calibration adjustments. R5 states:

"R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct any identified Unresolved Maintenance Issues."

Also, when a failure occurs in a Protection System, power system security may be comprised, and notification of the failure must be conducted in accordance with relevant NERC standards.

If I show the protective device out of service while it is being repaired, then can I add it back as a new protective device when it returns? If not, my relay testing history would show that I was out of compliance for the last maintenance cycle.

The maintenance and testing requirements (R5) state "…shall demonstrate efforts to correct any identified Unresolved Maintenance Issues..." The type of corrective activity is not stated; however, it could include repairs or replacements.

Your documentation requirements will increase, of course, to demonstrate that your device tested bad and had corrective actions initiated. Your regional entity might ask about the status of your corrective actions.

13. Self-Monitoring Capabilities and Limitations

Microprocessor relay proponents have cited the self-monitoring capabilities of these products for nearly 20 years. Theoretically, any element that is monitored does not need a periodic manual test. A problem today is that the community of manufacturers and users has not created clear documentation of exactly what is and is not monitored. Some unmonitored but critical elements are buried in installed systems that are described as self-monitoring.

To utilize the extended time intervals allowed by monitoring, the user must document that the monitoring attributes of the device match the minimum requirements listed in the Table 1.

Until users are able to document how all parts of a system which are required for the protective functions are monitored or verified (with help from manufacturers), they must continue with the unmonitored intervals established in Tables 1, 3, 4 and 5 and any associated sub-tables.

Going forward, manufacturers and users can develop mappings of the monitoring within relays, and monitoring coverage by the relay of user circuits connected to the relay terminals.

To enable the use of the most extensive monitoring (and never again have a hands-on maintenance requirement), the manufacturers of the microprocessor-based self-monitoring components in the Protection System should publish for the user a document or map that shows:

- How all internal elements of the product are monitored for any failure that could impact Protection System performance.
- Which connected circuits are monitored by checks implemented within the product; how to connect and set the product to assure monitoring of these connected circuits; and what circuits or potential problems are not monitored.

This manufacturer's information can be used by the registered entity to document compliance of the monitoring attributes requirements by:

- Presenting or referencing the product manufacturer's documents.
- Explaining in a system design document the mapping of how every component and circuit that is critical to protection is monitored by the microprocessor product(s) or by other design features.
- Extending the monitoring to include the alarm transmission Facilities through which failures are reported within a given time frame to allocate where action can be taken to initiate resolution of the alarm attributed to an Unresolved Maintenance Issue, so that failures of monitoring or alarming systems also lead to alarms and action.
- Documenting the plans for verification of any unmonitored components according to the requirements of Tables 1, 3, 4 and 5 and any associated sub-tables.

13.1 Frequently Asked Questions:

I can't figure out how to demonstrate compliance with the requirements for the highest level of monitoring of Protection Systems. Why does this Maintenance Standard describe a maintenance program approach I cannot achieve?

Demonstrating compliance with the requirements for the highest level of monitoring any particular component of Protection Systems is likely to be very involved, and may include detailed manufacturer documentation of complete internal monitoring within a device, comprehensive design drawing reviews, and other detailed documentation. This standard does not presume to specify what documentation must be developed; only that it must be documented.

There may actually be some equipment available that is capable of meeting these highest levels of monitoring criteria, in which case it may be maintained according to the highest level of monitoring shown on the Tables. However, even if there is no equipment available today that can meet this level of monitoring, the standard establishes the necessary requirements for when such equipment becomes available.

By creating a roadmap for development, this provision makes the standard technology-neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

14. Notification of Protection System or Automatic Reclosing Failures

When a failure occurs in a Protection System or Automatic Reclosing, power system security may be compromised, and notification of the failure must be conducted in accordance with relevant NERC standard(s). Knowledge of the failure may impact the system operator's decisions on acceptable Loading conditions.

This formal reporting of the failure and repair status to the system operator by the Protection System or Automatic Reclosing owner also encourages the system owner to execute repairs as rapidly as possible. In some cases, a microprocessor relay or carrier set can be replaced in hours; wiring termination failures may be repaired in a similar time frame. On the other hand, a component in an electromechanical or early-generation electronic relay may be difficult to find and may hold up repair for weeks. In some situations, the owner may have to resort to a temporary protection panel, or complete panel replacement.

15. Maintenance Activities

Some specific maintenance activities are a requirement to ensure reliability. An example would be that a BES entity could be prudent in its protective relay maintenance, but if its battery maintenance program is lacking, then reliability could still suffer. The NERC glossary outlines a Protection System as containing specific components. PRC-005-4 requires specific maintenance activities be accomplished within a specific time interval. As noted previously, higher technology equipment can contain integral monitoring capability that actually performs maintenance verification activities routinely and often; therefore, *manual intervention* to perform certain activities on these type components may not be needed.

15.1 Protective Relays (Table 1-1)

These relays are defined as the devices that receive the input signal from the current and voltage sensing devices and are used to isolate a Faulted Element of the BES. Devices that sense thermal, vibration, seismic, gas, or any other non-electrical inputs are excluded.

Non-microprocessor based equipment is treated differently than microprocessor-based equipment in the following ways; the relays should meet the asset owners' tolerances:

- Non-microprocessor devices must be tested with voltage and/or current applied to the device.
- Microprocessor devices may be tested through the integral testing of the device.
    - There is no specific protective relay commissioning test or relay routine test mandated.
    - There is no specific documentation mandated.

15.1.1 Frequently Asked Questions:

What calibration tolerance should be applied on electromechanical relays?

Each entity establishes their own acceptable tolerances when applying protective relaying on their system. For some Protection System components, adjustment is required to bring measurement accuracy within the parameters established by the asset owner based on the specific application of the component. A calibration failure is the result if testing finds the specified parameters to be out of tolerance.

15.2 Voltage & Current Sensing Devices (Table 1-3)

These are the current and voltage sensing devices, usually known as instrument transformers. There is presently a technology available (fiber-optic Hall-effect) that does not utilize conventional transformer technology; these devices and other technologies that produce quantities that represent the primary values of voltage and current are considered to be a type of voltage and current sensing devices included in this standard.

The intent of the maintenance activity is to verify the input to the protective relay from the device that produces the current or voltage signal sample.

There is no specific test mandated for these components. The important thing about these signals is to know that the expected output from these components actually reaches the protective relay. Therefore, the proof of the proper operation of these components also demonstrates the integrity of the wiring (or other medium used to convey the signal) from the current and voltage sensing device, all the way to the protective relay. The following observations apply:

- There is no specific ratio test, routine test or commissioning test mandated.
- There is no specific documentation mandated.
- It is required that the signal be present at the relay.
- This expectation can be arrived at from any of a number of means; including, but not limited to, the following: By calculation, by comparison to other circuits, by commissioning tests, by thorough inspection, or by any means needed to verify the circuit meets the asset owner's Protection System maintenance program.
- An example of testing might be a saturation test of a CT with the test values applied at the relay panel; this, therefore, tests the CT, as well as the wiring from the relay all the back to the CT.
- Another possible test is to measure the signal from the voltage and/or current sensing devices, during Load conditions, at the input to the relay.
- Another example of testing the various voltage and/or current sensing devices is to query the microprocessor relay for the Real-time Loading; this can then be compared to other devices to verify the quantities applied to this relay. Since the input devices have supplied the proper values to the protective relay, then the verification activity has been satisfied. Thus, event reports (and oscillographs) can be used to verify that the voltage and current sensing devices are performing satisfactorily.
- Still another method is to measure total watts and VArs around the entire bus; this should add up to zero watts and zero VArs, thus proving the voltage and/or current sensing devices system throughout the bus.
- Another method for proving the voltage and/or current-sensing devices is to complete commissioning tests on all of the transformers, cabling, fuses and wiring.
- Any other method that verifies the input to the protective relay from the device that produces the current or voltage signal sample.

15.2.1 Frequently Asked Questions:

What is meant by "… verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" Do we need to perform ratio, polarity and saturation tests every few years?

No. You must verify that the protective relay is receiving the expected values from the voltage and current-sensing devices (typically voltage and current transformers). This can be as difficult as is proposed by the question (with additional testing on the cabling and substation wiring to ensure that the values arrive at the relays); or simplicity can be achieved by other verification methods. While some examples follow, these are not intended to represent an all-inclusive list; technology advances and ingenuity should not be excluded from making comparisons and verifications:

- Compare the secondary values, at the relay, to a metering circuit, fed by different current transformers, monitoring the same line as the questioned relay circuit.
- Compare the individual phase secondary values at the relay panel (with additional testing on the panel wiring to ensure that the values arrive at those relays) with the other phases, and verify that residual currents are within expected bounds.
- Observe all three phase currents and the residual current at the relay panel with an oscilloscope, observing comparable magnitudes and proper phase relationship, with additional testing on the panel wiring to ensure that the values arrive at the relays.
- Compare the values, as determined by the questioned relay (such as, but not limited to, a query to the microprocessor relay) to another protective relay monitoring the same line, with currents supplied by different CTs.
- Compare the secondary values, at the relay with values measured by test instruments (such as, but not limited to multi-meters, voltmeter, clamp-on ammeters, etc.) and verified by calculations and known ratios to be the values expected. For example, a single PT on a 100KV bus will have a specific secondary value that, when multiplied by the PT ratio, arrives at the expected bus value of 100KV.
- Query SCADA for the power flows at the far end of the line protected by the questioned relay, compare those SCADA values to the values as determined by the questioned relay.
- Totalize the Watts and VARs on the bus and compare the totals to the values as seen by the questioned relay.

The point of the verification procedure is to ensure that all of the individual components are functioning properly; and that an ongoing proactive procedure is in place to re-check the various components of the protective relay measuring Systems.

Is wiring insulation or hi-pot testing required by this Maintenance Standard?

No, wiring insulation and equipment hi-pot testing are not specifically required by the Maintenance Standard. However, if the method of verifying CT and PT inputs to the relay involves some other method than actual observation of current and voltage transformer secondary inputs to the relay, it might be necessary to perform some sort of cable integrity test to verify that the instrument transformer secondary signals are actually making it to the relay and not being

shunted off to ground. For instance, you could use CT excitation tests and PT turns ratio tests and compare to baseline values to verify that the instrument transformer outputs are acceptable. However, to conclude that these acceptable transformer instrument output signals are actually making it to the relay inputs, it also would be necessary to verify the insulation of the wiring between the instrument transformer and the relay.

My plant generator and transformer relays are electromechanical and do not have metering functions, as do microprocessor- based relays. In order for me to compare the instrument transformer inputs to these relays to the secondary values of other metered instrument transformers monitoring the same primary voltage and current signals, it would be necessary to temporarily connect test equipment, like voltmeters and clamp on ammeters, to measure the input signals to the relays. This practice seems very risky, and a plant trip could result if the technician were to make an error while measuring these current and voltage signals. How can I avoid this risk? Also, what if no other instrument transformers are available which monitor the same primary voltage or current signal?

Comparing the input signals to the relays to the outputs of other independent instrument transformers monitoring the same primary current or voltage is just one method of verifying the instrument transformer inputs to the relays, but is not required by the standard. Plants can choose how to best manage their risk. If online testing is deemed too risky, offline tests, such as, but not limited to, CT excitation test and PT turns ratio tests can be compared to baseline data and be used in conjunction with CT and PT secondary wiring insulation verification tests to adequately "verify the current and voltage circuit inputs from the voltage and current sensing devices to the protective relays …" while eliminating the risk of tripping an in service generator or transformer. Similarly, this same offline test methodology can be used to verify the relay input voltage and current signals to relays when there are no other instrument transformers monitoring available for purposes of signal comparison.

15.3 Control circuitry associated with protective functions (Table 1-5)

This component of Protection Systems includes the trip coil(s) of the circuit breaker, circuit switcher or any other interrupting device. It includes the wiring from the batteries to the relays. It includes the wiring (or other signal conveyance) from every trip output to every trip coil. It includes any device needed for the correct processing of the needed trip signal to the trip coil of the interrupting device; this requirement is meant to capture inputs and outputs to and from a protective relay that are necessary for the correct operation of the protective functions. In short, every trip path must be verified; the method of verification is optional to the asset owner. An example of testing methods to accomplish this might be to verify, with a volt-meter, the existence of the proper voltage at the open contacts, the open circuited input circuit and at the trip coil(s). As every parallel trip path has similar failure modes, each trip path from relay to trip coil must be verified. Each trip coil must be tested to trip the circuit breaker (or other interrupting device) at least once. There is a requirement to operate the circuit breaker (or other interrupting device) at least once every six years as part of the complete functional test. If a suitable monitoring system is installed that verifies every parallel trip path, then the manual-intervention testing of those parallel trip paths can be eliminated; however, the actual operation of the circuit breaker must still occur at least once every six years. This six-year tripping requirement can be completed as easily as tracking the Real-time Fault-clearing operations on the circuit breaker, or tracking the trip coil(s) operation(s) during circuit breaker routine maintenance actions.

The circuit-interrupting device should not be confused with a motor-operated disconnect. The intent of this standard is to require maintenance intervals and activities on Protection Systems equipment, and not just all system isolating equipment.

It is necessary, however, to classify a device that actuates a high-speed auto-closing ground switch as an interrupting device, if this ground switch is utilized in a Protection System and forces a ground Fault to occur that then results in an expected Protection System operation to clear the forced ground Fault. The SDT believes that this is essentially a transferred-tripping device without the use of communications equipment. If this high-speed ground switch is "…designed to provide protection for the BES…" then this device needs to be treated as any other Protection System component. The control circuitry would have to be tested within 12 years, and any electromechanically operated device will have to be tested every six years. If the spring-operated ground switch can be disconnected from the solenoid triggering unit, then the solenoid triggering unit can easily be tested without the actual closing of the ground blade.

The dc control circuitry also includes each auxiliary tripping relay (94) and each lock-out relay (86) that may exist in any particular trip scheme. If the lock-out relays (86) are electromechanical type components, then they must be trip tested. The PSMT SDT considers these components to share some similarities in failure modes as electromechanical protective relays; as such, there is a six-year maximum interval between mandated maintenance tasks unless PBM is applied.

Contacts of the 86 and/or 94 that pass the trip current on to the circuit interrupting device trip coils will have to be checked as part of the 12 year requirement. Contacts of the 86 and/or 94 lock relay that operate non-BES interrupting devices are not required. Normally-open contacts that are not used to pass a trip signal and normally-closed contacts do not have to be verified. Verification of the tripping paths is the requirement.

New technology is also accommodated here; there are some tripping systems that have replaced the traditional hard-wired trip circuitry with other methods of trip-signal conveyance such as fiber-optics. It is the intent of the PSMT SDT to include this, and any other, technology that is used to convey a trip signal from a protective relay to a circuit breaker (or other interrupting device) within this category of equipment. The requirement for these systems is verification of the tripping path.

Monitoring of the control circuit integrity allows for no maintenance activity on the control circuit (excluding the requirement to operate trip coils and electromechanical lockout and/or tripping auxiliary relays). Monitoring of integrity means to monitor for continuity and/or presence of voltage on each trip path. For Ethernet or fiber-optic control systems, monitoring of integrity means to monitor communication ability between the relay and the circuit breaker.

15.3.1 Frequently Asked Questions:

Is it permissible to verify circuit breaker tripping at a different time (and interval) than when we verify the protective relays and the instrument transformers?

Yes, provided the entire Protective System is tested within the individual component's maximum allowable testing intervals.

The Protection System Maintenance Standard describes requirements for verifying the tripping of circuit breakers. What is this telling me about maintenance of circuit breakers?

Requirements in PRC-005-4 are intended to verify the integrity of tripping circuits, including the breaker trip coil, as well as the presence of auxiliary supply (usually a battery) for energizing the trip coil if a protection function operates. Beyond this, PRC-005-4 sets no requirements for verifying circuit breaker performance, or for maintenance of the circuit breaker.

How do I test each dc Control Circuit trip path, as established in Table 1-5 "Protection System Control Circuitry (Trip coils and auxiliary relays)"?

Table 1-5 specifies that each breaker trip coil and lockout relays that carry trip current to a trip coil must be operated within the specified time period. The required operations may be via targeted maintenance activities, or by documented operation of these devices for other purposes such as Fault clearing.

Are high-speed ground switch trip coils included in the dc control circuitry?

Yes. PRC-005-4 includes high-speed grounding switch trip coils within the dc control circuitry to the degree that the initiating Protection Systems are characterized as "transmission Protection Systems."

Does the control circuitry and trip coil of a non-BES breaker, tripped via a BES protection component, have to be tested per Table 1.5? (Refer to Table 3 for examples 1 and 2) Example 1: A non-BES circuit breaker that is tripped via a Protection System to which PRC-005-4 applies might be (but is not limited to) a 12.5KV circuit breaker feeding (non-black-start) radial Loads but has a trip that originates from an under-frequency (81) relay.

- The relay must be verified.
- The voltage signal to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

Example 2: A Transmission Owner may have a non-BES breaker that is tripped via a Protection System to which PRC-005-4 applies, which may be (but is not limited to) a 13.8 KV circuit breaker feeding (non-black-start) radial Loads but has a trip that originates from a BES 115KV line relay.

- The relay must be verified
- The voltage signal to the relay must be verified
- All of the relevant dc supply tests still apply

- The unmonitored trip circuit between the relay and any lock-out (86) or auxiliary (94) relay must be verified every 12 years
- The unmonitored trip circuit between the lock-out (86) (or auxiliary (94)) relay and the non-BES breaker does not have to be proven with an electrical trip
- In the case where there is no lockout (86) or auxiliary (94) tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip

Example 3: A Generator Owner may have a non-BES circuit breaker that is tripped via a Protection System to which PRC-005-4 applies, such as the generator field breaker and low-side breakers on station service/excitation transformers connected to the generator bus.

Trip testing of the generator field breaker and low side station service/excitation transformer breaker(s) via lockout or auxiliary tripping relays are not required since these breakers may be associated with radially fed loads and are not considered to be BES breakers. An example of an otherwise non-BES circuit breaker that is tripped via a BES protection component might be (but is not limited to) a 6.9kV station service transformer source circuit breaker but has a trip that originates from a generator differential (87) relay.

- The differential relay must be verified.
- The current signals to the relay must be verified.
- All of the relevant dc supply tests still apply.
- The unmonitored trip circuit between the relay and any lock-out or auxiliary relay must be verified every 12 years.
- The unmonitored trip circuit between the lock-out (or auxiliary relay) and the non-BES breaker does not have to be proven with an electrical trip.
- In the case where there is no lock-out or auxiliary tripping relay used, the trip circuit to the non-BES breaker does not have to be proven with an electrical trip.
- The trip coil of the non-BES circuit breaker does not have to be individually proven with an electrical trip.

However, it is very prudent to verify the tripping of such breakers for the integrity of the overall generation plant.

Do I have to verify operation of breaker "a" contacts or any other normally closed auxiliary contacts in the trip path of each breaker as part of my control circuit test?

Operation of normally-closed contacts does not have to be verified. Verification of the tripping paths is the requirement. The continuity of the normally closed contacts will be verified when the tripping path is verified.

15.4 Batteries and DC Supplies (Table 1-4)

The NERC definition of a Protection System is:

- Protective relays which respond to electrical quantities,

- Communications Systems necessary for correct operation of protective functions,
- Voltage and current sensing devices providing inputs to protective relays,
- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

The station battery is not the only component that provides dc power to a Protection System. In the new definition for Protection System, "station batteries" are replaced with "station dc supply" to make the battery charger and dc producing stored energy devices (that are not a battery) part of the Protection System that must be maintained.

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal. Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. An open battery string will be an unavailable power source in the event of loss of the battery charger.

Batteries cannot be a unique population segment of a Performance-Based Maintenance Program (PBM) because there are too many variables in the electrochemical process to completely isolate all of the performance-changing criteria necessary for using PBM on battery Systems. However, nothing precludes the use of a PBM process for any other part of a dc supply besides the batteries themselves.

15.4.1 Frequently Asked Questions:

What constitutes the station dc supply, as mentioned in the definition of Protective System?

The previous definition of Protection System includes batteries, but leaves out chargers. The latest definition includes chargers, as well as dc systems that do not utilize batteries. This revision of PRC-005-4 is intended to capture these devices that were not included under the previous definition. The station direct current (dc) supply normally consists of two components: the battery charger and the station battery itself. There are also emerging technologies that provide a source of dc supply that does not include either a battery or charger.

Battery Charger - The battery charger is supplied by an available ac source. At a minimum, the battery charger must be sized to charge the battery (after discharge) and supply the constant dc load. In many cases, it may be sized also to provide sufficient dc current to handle the higher energy requirements of tripping breakers and switches when actuated by the protective relays in the Protection System.

Station Battery - Station batteries provide the dc power required for tripping and for supplying normal dc power to the station in the event of loss of the battery charger. There are several technologies of battery that require unique forms of maintenance as established in Table 1-4.

Emerging Technologies - Station dc supplies are currently being developed that use other energy storage technologies besides the station battery to prevent loss of the station dc supply when ac power is lost. Maintenance of these station dc supplies will require different kinds of tests and inspections. Table 1-4 presents maintenance activities and maximum allowable testing intervals for these new station dc supply technologies. However, because these technologies are relatively new, the maintenance activities for these station dc supplies may change over time.

What did the PSMT SDT mean by "continuity" of the dc supply?

The PSMT SDT recognizes that there are several technological advances in equipment and testing procedures that allow the owner to choose how to verify that a battery string is free of open circuits. The term "continuity" was introduced into the standard to allow the owner to choose how to verify continuity (no open circuits) of a battery set by various methods, and not to limit the owner to other conventional methods of showing continuity – lack of an open circuit. Continuity, as used in Table 1-4 of the standard, refers to verifying that there is a continuous current path from the positive terminal of the station battery set to the negative terminal (no open circuit). Without verifying continuity of a station battery, there is no way to determine that the station battery is available to supply dc power to the station. Whether it is caused from an open cell or a bad external connection, an open battery string will be an unavailable power source in the event of loss of the battery charger.

The current path through a station battery from its positive to its negative connection to the dc control circuits is composed of two types of elements. These path elements are the electrochemical path through each of its cells and all of the internal and external metallic connections and terminations of the batteries in the battery set. If there is loss of continuity (an open circuit) in any part of the electrochemical or metallic path, the battery set will not be available for service. In the event of the loss of the ac source or battery charger, the battery must be capable of supplying dc current, both for continuous dc loads and for tripping breakers and switches. Without continuity, the battery cannot perform this function.
At generating stations and large transmission stations where battery chargers are capable of handling the maximum current required by the Protection System, there are still problems that could potentially occur when the continuity through the connected battery is interrupted.

- Many battery chargers produce harmonics which can cause failure of dc power supplies in microprocessor-based protective relays and other electronic devices connected to station dc supply. In these cases, the substation battery serves as a filter for these harmonics. With the loss of continuity in the battery, the filter provided by the battery is no longer present.
- Loss of electrical continuity of the station battery will cause, in most battery chargers, regardless of the battery charger's output current capability, a delayed response in full output current from the charger. Almost all chargers have an intentional one- to two-second delay to switch from a low substation dc load current to the maximum output of the charger. This delay would cause the opening of circuit breakers to be delayed, which could violate system performance standards.

Monitoring of the station dc supply voltage will not indicate that there is a problem with the dc current path through the battery, unless the battery charger is taken out of service. At that time,

a break in the continuity of the station battery current path will be revealed because there will be no voltage on the station dc circuitry. This particular test method, while proving battery continuity, may not be acceptable to all installations.

Although the standard prescribes what must be accomplished during the maintenance activity, it does not prescribe how the maintenance activity should be accomplished. There are several methods that can be used to verify the electrical continuity of the battery. These are not the only possible methods, simply a sampling of some methods:

- One method is to measure that there is current flowing through the battery itself by a simple clamp on milliamp-range ammeter. A battery is always either charging or discharging. Even when a battery is charged, there is still a measurable float charge current that can be detected to verify that there is continuity in the electrical path through the battery.
- A simple test for continuity is to remove the battery charger from service and verify that the battery provides voltage and current to the dc system. However, the behavior of the various dc-supplied equipment in the station should be considered before using this approach.
- Manufacturers of microprocessor-controlled battery chargers have developed methods for their equipment to periodically (or continuously) test for battery continuity. For example, one manufacturer periodically reduces the float voltage on the battery until current from the battery to the dc load can be measured to confirm continuity.
- Applying test current (as in some ohmic testing devices, or devices for locating dc grounds) will provide a current that when measured elsewhere in the string, will prove that the circuit is continuous.
- Internal ohmic measurements of the cells and units of lead-acid batteries (VRLA & VLA) can detect lack of continuity within the cells of a battery string; and when used in conjunction with resistance measurements of the battery's external connections, can prove continuity. Also some methods of taking internal ohmic measurements, by their very nature, can prove the continuity of a battery string without having to use the results of resistance measurements of the external connections.
- Specific gravity tests could infer continuity because without continuity there could be no charging occurring; and if there is no charging, then specific gravity will go down below acceptable levels over time.

No matter how the electrical continuity of a battery set is verified, it is a necessary maintenance activity that must be performed at the intervals prescribed by Table 1-4 to insure that the station dc supply has a path that can provide the required current to the Protection System at all times.

When should I check the station batteries to see if they have sufficient energy to perform as manufactured?

The answer to this question depends on the type of battery (valve-regulated lead-acid, vented lead-acid, or nickel-cadmium) and the maintenance activity chosen.

For example, if you have a valve-regulated lead-acid (VRLA) station battery, and you have chosen to evaluate the measured cell/unit internal ohmic values to the battery cell's baseline, you will have to perform verification at a maximum maintenance interval of no greater than

every six months. While this interval might seem to be quite short, keep in mind that the six-month interval is important for VRLA batteries; this interval provides an accumulation of data that better shows when a VRLA battery is incapable of performing as manufactured.

If, for a VRLA station battery, you choose to conduct a performance capacity test on the entire station battery as the maintenance activity, then you will have to perform verification at a maximum maintenance interval of no greater than every three calendar years.

How is a baseline established for cell/unit internal ohmic measurements?

Establishment of cell/unit internal ohmic baseline measurements should be completed when lead-acid batteries are newly installed. To ensure that the baseline ohmic cell/unit values are most indicative of the station battery's ability to perform as manufactured, they should be made at some point in time after the installation to allow the cell chemistry to stabilize after the initial freshening charge. An accepted industry practice for establishing baseline values is after six-months of installation, with the battery fully charged and in service. However, it is recommended that each owner, when establishing a baseline, should consult the battery manufacturer for specific instructions on establishing an ohmic baseline for their product, if available.

When internal ohmic measurements are taken, the same make/model test equipment should be used to establish the baseline and used for the future trending of the cells internal ohmic measurements because of variances in test equipment and the type of ohmic measurement used by different manufacturer's equipment. Keep in mind that one manufacturer's "Conductance" test equipment does not produce similar results as another manufacturer's "Conductance" test equipment, even though both manufacturers have produced "Ohmic" test equipment. Therefore, for meaningful results to an established baseline, the same make/model of instrument should be used.

For all new installations of valve-regulated lead-acid (VRLA) batteries and vented lead-acid (VLA) batteries, where trending of the cells internal ohmic measurements to a baseline are to be used to determine the ability of the station battery to perform as manufactured, the establishment of the baseline, as described above, should be followed at the time of installation to insure the most accurate trending of the cell/unit. However, often for older VRLA batteries, the owners of the station batteries have not established a baseline at installation. Also for owners of VLA batteries who want to establish a maintenance activity which requires trending of measured ohmic values to a baseline, there was typically no baseline established at installation of the station battery to trend to.

To resolve the problem of the unavailability of baseline internal ohmic measurements for the individual cell/unit of a station battery, many manufacturers of internal ohmic measurement devices have established libraries of baseline values for VRLA and VLA batteries using their testing device. Also, several of the battery manufacturers have libraries of baselines for their products that can be used to trend to. However, it is important that when using battery manufacturer-supplied data that it is verified that the baseline readings to be used were taken with the same ohmic testing device that will be used for future measurements (for example "Conductance Readings" from one manufacturer's test equipment do not correlate to "Impedance Readings" from a different manufacturer's test equipment). Although many manufacturers may have provided baseline values, which will allow trending of the internal ohmic measurements over the remaining life of a station battery, these baselines are not the actual cell/unit measurements for

the battery being trended. It is important to have a baseline tailored to the station battery to more accurately use the tool of ohmic measurement trending. That more customized baseline can only be created by following the establishment of a baseline for each cell/unit at the time of installation of the station battery.

Why determine the State of Charge?

Even though there is no present requirement to check the state of charge of a battery, it can be a very useful tool in determining the overall condition of a battery system. The following discussions are offered as a general reference.

When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. It is necessary to determine if the state of charge has dropped to an unacceptable level.

What is State of Charge and how can it be determined in a station battery?

The state of charge of a battery refers to the ratio of residual capacity at a given instant to the maximum capacity available from the battery. When a battery is fully charged, the battery is available to deliver its existing capacity. As a battery is discharged, its ability to deliver its maximum available capacity is diminished. Knowing the amount of energy left in a battery compared with the energy it had when it was fully charged gives the user an indication of how much longer a battery will continue to perform before it needs recharging.

For vented lead-acid (VLA) batteries which use accessible liquid electrolyte, a hydrometer can be used to test the specific gravity of each cell as a measure of its state of charge. The hydrometer depends on measuring changes in the weight of the active chemicals. As the battery discharges, the active electrolyte, sulfuric acid, is consumed and the concentration of the sulfuric acid in water is reduced. This, in turn, reduces the specific gravity of the solution in direct proportion to the state of charge. The actual specific gravity of the electrolyte can, therefore, be used as an indication of the state of charge of the battery. Hydrometer readings may not tell the whole story, as it takes a while for the acid to get mixed up in the cells of a VLA battery. If measured right after charging, you might see high specific gravity readings at the top of the cell, even though it is much less at the bottom. Conversely, if taken shortly after adding water to the cell, the specific gravity readings near the top of the cell will be lower than those at the bottom.

Nickel-cadmium batteries, where the specific gravity of the electrolyte does not change during battery charge and discharge, and valve-regulated lead-acid (VRLA) batteries, where the electrolyte is not accessible, cannot have their state of charge determined by specific gravity readings. For these two types of batteries, and for VLA batteries also, where another method besides taking hydrometer readings is desired, the state of charge may be determined by taking voltage and current readings at the battery terminals. The methods employed to obtain accurate readings vary for the different battery types. Manufacturers' information and IEEE guidelines can be consulted for specifics; (see IEEE 1106 Annex B for Nickel Cadmium batteries, IEEE 1188 Annex A for VRLA batteries and IEEE 450 for VLA batteries.

Why determine the Connection Resistance?

High connection resistance can cause abnormal voltage drop or excessive heating during discharge of a station battery. During periods of a high rate of discharge of the station battery, a very high resistance can cause severe damage. The maintenance requirement to verify battery terminal connection resistance in Table 1-4 is established to verify that the integrity of all battery electrical connections is acceptable. This verification includes cell-to-cell (intercell) and external

circuit terminations. Your method of checking for acceptable values of intercell and terminal connection resistance could be by individual readings, or a combination of the two. There are test methods presently that can read post termination resistances and resistance values between external posts. There are also test methods presently available that take a combination reading of the post termination connection resistance plus the intercell resistance value plus the post termination connection resistance value. Either of the two methods, or any other method, that can show if the adequacy of connections at the battery posts is acceptable.

Adequacy of the electrical terminations can be determined by comparing resistance measurements for all connections taken at the time of station battery's installation to the same resistance measurements taken at the maintenance interval chosen, not to exceed the maximum maintenance interval of Table 1-4. Trending of the interval measurements to the baseline measurements will identify any degradation in the battery connections. When the connection resistance values exceed the acceptance criteria for the connection, the connection is typically disassembled, cleaned, reassembled and measurements taken to verify that the measurements are adequate when compared to the baseline readings.

What conditions should be inspected for visible battery cells?

The maintenance requirement to inspect the cell condition of all station battery cells where the cells are visible is a maintenance requirement of Table 1-4. Station batteries are different from any other component in the Protection Station because they are a perishable product due to the electrochemical process which is used to produce dc electrical current and voltage. This inspection is a detailed visual inspection of the cells for abnormalities that occur in the aging process of the cell. In VLA battery visual inspections, some of the things that the inspector is typically looking for on the plates are signs of sulfation of the plates, abnormal colors (which are an indicator of sulfation or possible copper contamination) and abnormal conditions such as cracked grids. The visual inspection could look for symptoms of hydration that would indicate that the battery has been left in a completely discharged state for a prolonged period. Besides looking at the plates for signs of aging, all internal connections, such as the bus bar connection to each plate, and the connections to all posts of the battery need to be visually inspected for abnormalities. In a complete visual inspection for the condition of the cell the cell plates, separators and sediment space of each cell must be looked at for signs of deterioration. An inspection of the station battery's cell condition also includes looking at all terminal posts and cell-to-cell electric connections to ensure they are corrosion free. The case of the battery containing the cell, or cells, must be inspected for cracks and electrolyte leaks through cracks and the post seals.

This maintenance activity cannot be extended beyond the maximum maintenance interval of Table 1-4 by a Performance-Based Maintenance Program (PBM) because of the electrochemical aging process of the station battery, nor can there be any monitoring associated with it because there must be a visual inspection involved in the activity. A remote visual inspection could possibly be done, but its interval must be no greater than the maximum maintenance interval of Table 1-4.

Why is it necessary to verify the battery string can perform as manufactured? I only care that the battery can trip the breaker, which means that the battery can perform as designed. I oversize my batteries so that even if the battery cannot perform as manufactured, it can still trip my breakers.

The fundamental answer to this question revolves around the concept of battery performance "as designed" vs. battery performance "as manufactured." The purpose of the various sections of Table 1-4 of this standard is to establish requirements for the Protection System owner to maintain the batteries, to ensure they will operate the equipment when there is an incident that requires dc power, and ensure the batteries will continue to provide adequate service until at least the next maintenance interval. To meet these goals, the correct battery has to be properly selected to meet the design parameters, and the battery has to deliver the power it was manufactured to provide.

When testing batteries, it may be difficult to determine the original design (i.e., load profile) of the dc system. This standard is not intended as a design document, and requirements relating to design are, therefore, not included.

Where the dc load profile is known, the best way to determine if the system will operate as designed is to conduct a service test on the battery. However, a service test alone might not fully determine if the battery is healthy. A battery with 50% capacity may be able to pass a service test, but the battery would be in a serious state of deterioration and could fail at some point in the near future.

To ensure that the battery will meet the required load profile and continue to meet the load profile until the next maintenance interval, the installed battery must be sized correctly (i.e., a correct design), and it must be in a good state of health. Since the design of the dc system is not within the scope of the standard, the only consistent and reliable method to ensure that the battery is in a good state of health is to confirm that it can perform as manufactured. If the battery can perform as manufactured and it has been designed properly, the system should operate properly until the next maintenance interval.

How do I verify the battery string can perform as manufactured?

Optimally, actual battery performance should be verified against the manufacturer's rating curves. The best practice for evaluating battery performance is via a performance test. However, due to both logistical and system reliability concerns, some Protection System owners prefer other methods to determine if a battery can perform as manufactured. There are several battery parameters that can be evaluated to determine if a battery can perform as manufactured. Ohmic measurements and float current are two examples of parameters that have been reported to assist in determining if a battery string can perform as manufactured.

The evaluation of battery parameters in determining battery health is a complex issue, and is not an exact science. This standard gives the user an opportunity to utilize other measured parameters to determine if the battery can perform as manufactured. It is the responsibility of the Protection System owner, however, to maintain a documented process that demonstrates the chosen parameter(s) and associated methodology used to determine if the battery string can perform as manufactured.

Whatever parameters are used to evaluate the battery (ohmic measurements, float current, float voltages, temperature, specific gravity, performance test, or combination thereof), the goal is to determine the value of the measurement (or the percentage change) at which the battery fails to perform as manufactured, or the point where the battery is deteriorating so rapidly that it will not perform as manufactured before the next maintenance interval.

This necessitates the need for establishing and documenting a baseline. A baseline may be required of every individual cell, a particular battery installation, or a specific make, model, or size of a cell. Given a consistent cell manufacturing process, it may be possible to establish a baseline number for the cell (make/model/type) and, therefore, a subsequent baseline for every installation would not be necessary. However, future installations of the same battery types should be spot-checked to ensure that your baseline remains applicable.

Consistent testing methods by trained personnel are essential. Moreover, it is essential that these technicians utilize the same make/model of ohmic test equipment each time readings are taken in order to establish a meaningful and accurate trend line against the established baseline. The type of probe and its location (post, connector, etc.) for the reading need to be the same for each subsequent test. The room temperature should be recorded with the readings for each test as well. Care should be taken to consider any factors that might lead a trending program to become invalid.

Float current along with other measureable parameters can be used in lieu of or in concert with ohmic measurement testing to measure the ability of a battery to perform as manufactured. The key to using any of these measurement parameters is to establish a baseline and the point where the reading indicates that the battery will not perform as manufactured.

The establishment of a baseline may be different for various types of cells and for different types of installations. In some cases, it may be possible to obtain a baseline number from the battery manufacturer, although it is much more likely that the baseline will have to be established after the installation is complete. To some degree, the battery may still be "forming" after installation; consequently, determining a stable baseline may not be possible until several months after the battery has been in service.

The most important part of this process is to determine the point where the ohmic reading (or other measured parameter(s)) indicates that the battery cannot perform as manufactured. That point could be an absolute number, an absolute change, or a percentage change of an established baseline.

Since there are no universally-accepted repositories of this information, the Protection System owner will have to determine the value/percentage where the battery cannot perform as manufactured (heretofore referred to as a failed cell). This is the most difficult and important part of the entire process.

To determine the point where the battery fails to perform as manufactured, it is helpful to have a history of a battery type, if the data includes the parameter(s) used to evaluate the battery's ability to perform as manufactured against the actual demonstrated performance/capacity of a battery/cell.

For example, when an ohmic reading has been recorded that the user suspects is indicating a failed cell, a performance test of that cell (or string) should be conducted in order to prove/quantify that the cell has failed. Through this process, the user needs to determine the ohmic value at which the performance of the cell has dropped below 80% of the manufactured, rated performance. It is likely that there may be a variation in ohmic readings that indicates a failed cell (possibly significant). It is prudent to use the most conservative values to determine the point at which the cell should be marked for replacement. Periodically, the user should

demonstrate that an “adequate” ohmic reading equates to an adequate battery performance (>80% of capacity).

Similarly, acceptance criteria for "good" and "failed" cells should be established for other parameters such as float current, specific gravity, etc., if used to determine the ability of a battery to function as designed.

What happens if I change the make/model of ohmic test equipment after the battery has been installed for a period of time?

If a user decides to switch testers, either voluntarily or because the equipment is not supported/sold any longer, the user may have to establish a new base line and new parameters that indicate when the battery no longer performs as manufactured. The user always has a choice to perform a capacity test in lieu of establishing new parameters.

What are some of the differences between lead-acid and nickel-cadmium batteries?

There is a marked difference in the aging process of lead acid and nickel-cadmium station batteries. The difference in the aging process of these two types of batteries is chiefly due to the electrochemical process of the battery type. Aging and eventual failure of lead acid batteries is due to expansion and corrosion of the positive grid structure, loss of positive plate active material, and loss of capacity caused by physical changes in the active material of the positive plates. In contrast, the primary failure of nickel-cadmium batteries is due to the gradual linear aging of the active materials in the plates. The electrolyte of a nickel-cadmium battery only facilitates the chemical reaction (it functions only to transfer ions between the positive and negative plates), but is not chemically altered during the process like the electrolyte of a lead acid battery. A lead acid battery experiences continued corrosion of the positive plate and grid structure throughout its operational life while a nickel-cadmium battery does not.

Changes to the properties of a lead acid battery when periodically measured and trended to a baseline, can indicate aging of the grid structure, positive plate deterioration, or changes in the active materials in the plate.

Because of the clear differences in the aging process of lead acid and nickel-cadmium batteries, there are no significantly measurable properties of the nickel-cadmium battery that can be measured at a periodic interval and trended to determine aging. For this reason, Table 1-4(c) (Protection System Station dc supply Using nickel-cadmium [NiCad] Batteries) only specifies one minimum maintenance activity and associated maximum maintenance interval necessary to verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance against the station battery baseline. This maintenance activity is to conduct a performance or modified performance capacity test of the entire battery bank.

Why in Table 1-4 of PRC-005-4 is there a maintenance activity to inspect the structural intergrity of the battery rack?

The purpose of this inspection is to verify that the battery rack is correctly installed and has no deterioration that could weaken its structural integrity.
Because the battery rack is specifically manufactured for the battery that is mounted on it, weakening of its structural members by rust or corrosion can physically jeopardize the battery.

What is required to comply with the “Unintentional dc Grounds” requirement?

In most cases, the first ground that appears on a battery is not a problem. It is the unintentional ground that appears on the opposite pole that becomes problematic. Even then many systems are designed to operate favorably under some unintentional dc ground situations. It is up to the owner of the Protection System to determine if corrective actions are needed on detected unintentional dc grounds. The standard merely requires that a check be made for the existence of unintentional dc grounds. Obviously, a "check-off" of some sort will have to be devised by the inspecting entity to document that a check is routinely done for unintentional dc grounds because of the possible consequences to the Protection System.

Where the standard refers to "all cells," is it sufficient to have a documentation method that refers to "all cells," or do we need to have separate documentation for every cell? For example, do I need 60 individual documented check-offs for good electrolyte level, or would a single check-off per bank be sufficient?

A single check-off per battery bank is sufficient for documentation, as long as the single check-off attests to checking all cells/units.

Does this standard refer to Station batteries or all batteries; for example, Communications Site Batteries?

This standard refers to Station Batteries. The drafting team does not believe that the scope of this standard refers to communications sites. The batteries covered under PRC-005-4 are the batteries that supply the trip current to the trip coils of the interrupting devices that are a part of the Protection System. The SDT believes that a loss of power to the communications systems at a remote site would cause the communications systems associated with protective relays to alarm at the substation. At this point, the corrective actions can be initiated.

What are cell/unit internal ohmic measurements?

With the introduction of Valve-Regulated Lead-Acid (VRLA) batteries to station dc supplies in the 1980's several of the standard maintenance tools that are used on Vented Lead-Acid (VLA) batteries were unable to be used on this new type of lead-acid battery to determine its state of health. The only tools that were available to give indication of the health of these new VRLA batteries were voltage readings of the total battery voltage, the voltage of the individual cells and periodic discharge tests.

In the search for a tool for determining the health of a VRLA battery several manufacturers studied the electrical model of a lead acid battery's current path through its cell. The overall battery current path consists of resistance and inductive and capacitive reactance. The inductive reactance in the current path through the battery is so minuscule when compared to the huge capacitive reactance of the cells that it is often ignored in most circuit models of the battery cell. Taking the basic model of a battery cell manufacturers of battery test equipment have developed and marketed testing devices to take measurements of the current path to detect degradation in the internal path through the cell.

In the battery industry, these various types of measurements are referred to as ohmic measurements. Terms used by the industry to describe ohmic measurements are ac conductance, ac impedance, and dc resistance. They are defined by the test equipment providers and IEEE and refer to the method of taking ohmic measurements of a lead acid battery. For example, in one manufacturer's ac conductance equipment measurements are taken by applying a voltage of a known frequency and amplitude across a cell or battery unit and observing the ac

current flow it produces in response to the voltage. A manufacturer of an ac impedance meter measures ac current of a known frequency and amplitude that is passed through the whole battery string and determines the impedances of each cell or unit by measuring the resultant ac voltage drop across them. On the other hand, dc resistance of a cell is measured by a third manufacturer's equipment by applying a dc load across the cell or unit and measuring the step change in both the voltage and current to calculate the internal dc resistance of the cell or unit.

It is important to note that because of the rapid development of the market for ohmic measurement devices, there were no standards developed or used to mandate the test signals used in making ohmic measurements. Manufacturers using proprietary methods and applying different frequencies and magnitudes for their signals have developed a diversity of measurement devices. This diversity in test signals coupled with the three different types of ohmic measurements techniques (impedance conductance and resistance) make it impossible to always get the same ohmic measurement for a cell with different ohmic measurement devices. However, IEEE has recognized the great value for choosing one device for ohmic measurement, no matter who makes it or the method to calculate the ohmic measurement. The only caution given by IEEE and the battery manufacturers is that when trending the cells of a lead acid station battery consistent ohmic measurement devices should be used to establish the baseline measurement and to trend the battery set for its entire life.

For VRLA batteries both IEEE Standard 1188 (Maintenance, Testing and Replacement of VRLA Batteries) and IEEE Standard 1187 (Installation Design and Installation of VRLA Batteries) recognize the importance of the maintenance activity of establishing a baseline for "cell/unit internal ohmic measurements (impedance, conductance and resistance)" and trending them at frequent intervals over the life of the battery. There are extensive discussions about the need for taking these measurements in these standards. IEEE Standard 1188 requires taking internal ohmic values as described in Annex C4 during regular inspections of the station battery. For VRLA batteries IEEE Standard 1188 in talking about the necessity of establishing a baseline and trending it over time says, "…depending on the degree of change a performance test, cell replacement or other corrective action may be necessary…" (IEEE std 1188-2005, C.4 page 18).

For VLA batteries IEEE Standard 484 (Installation of VLA batteries) gives several guidelines about establishing baseline measurements on newly installed lead acid stationary batteries. The standard also discusses the need to look for significant changes in the ohmic measurements, the caution that measurement data will differ with each type of model of instrument used, and lists a number of factors that affect ohmic measurements.

At the beginning of the 21st century, EPRI conducted a series of extensive studies to determine the relationship of internal ohmic measurements to the capacity of a lead acid battery cell. The studies indicated that internal ohmic measurements were in fact a good indicator of a lead acid battery cell's capacity, but because users often were only interested in the total station battery capacity and the technology does not precisely predict overall battery capacity, if a user only needs "an accurate measure of the overall battery capacity," they should "perform a battery capacity test."

Prior to the EPRI studies some large and small companies which owned and maintained station dc supplies in NERC Protection Systems developed maintenance programs where trending of ohmic measurements of cells/units of the station's battery became the maintenance activity for determining if the station battery could perform as manufactured. By evaluation of the trending

of the ohmic measurements over time, the owner could track the performance of the individual components of the station battery and determine if a total station battery or components of it required capacity testing, removal, replacement or in many instances replacement of the entire station battery. By taking this condition based approach these owners have eliminated having to perform capacity testing at prescribed intervals to determine if a battery needs to be replaced and are still able to effectively determine if a station battery can perform as manufactured.

My VRLA batteries have multiple-cells within an individual battery jar (or unit); how am I expected to comply with the cell-to-cell ohmic measurement requirements on these units that I cannot get to?

Measurement of cell/unit (not all batteries allow access to "individual cells" some "units" or jars may have multiple cells within a jar) internal ohmic values of all types of lead acid batteries where the cells of the battery are not visible is a station dc supply maintenance activity in Table 1-4. In cases where individual cells in a multi-cell unit are inaccessible, an ohmic measurement of the entire unit may be made.

I have a concern about my batteries being used to support additional auxiliary loads beyond my protection control systems in a generation station. Is ohmic measurement testing sufficient for my needs?

While this standard is focused on addressing requirements for Protection Systems, if batteries are used to service other load requirements beyond that of Protection Systems (e.g. pumps, valves, inverter loads), the functional entity may consider additional testing to confirm that the capacity of the battery is sufficient to support all loads.

Why verify voltage?

There are two required maintenance activities associated with verification of dc voltages in Table 1-4. These two required activities are to verify station dc supply voltage and float voltage of the battery charger, and have different maximum maintenance intervals. Both of these voltage verification requirements relate directly to the battery charger maintenance.

The verification of the dc supply voltage is simply an observation of battery voltage to prove that the charger has not been lost or is not malfunctioning; a reading taken from the battery charger panel meter or even SCADA values of the dc voltage could be some of the ways that one could satisfy the requirements. Low battery voltage below float voltage indicates that the battery may be on discharge and, if not corrected, the station battery could discharge down to some extremely low value that will not operate the Protection System. High voltage, close to or above the maximum allowable dc voltage for equipment connected to the station dc supply indicates the battery charger may be malfunctioning by producing high dc voltage levels on the Protection System. If corrective actions are not taken to bring the high voltage down, the dc power supplies and other electronic devices connected to the station dc supply may be damaged. The maintenance activity of verifying the float voltage of the battery charger is not to prove that a charger is lost or producing high voltages on the station dc supply, but rather to prove that the charger is properly floating the battery within the proper voltage limits. As above, there are many ways that this requirement can be met.

Why check for the electrolyte level?

In vented lead-acid (VLA) and nickel-cadmium (NiCad) batteries the visible electrolyte level must be checked as one of the required maintenance activities that must be performed at an interval that is equal to or less than the maximum maintenance interval of Table 1-4. Because the electrolyte level in valve-regulated lead-acid (VRLA) batteries cannot be observed, there is no maintenance activity listed in Table 1-4 of the standard for checking the electrolyte level. Low electrolyte level of any cell of a VLA or NiCad station battery is a condition requiring correction. Typically, the electrolyte level should be returned to an acceptable level for both types of batteries (VLA and NiCad) by adding distilled or other approved-quality water to the cell.

Often people confuse the interval for watering all cells required due to evaporation of the electrolyte in the station battery cells with the maximum maintenance interval required to check the electrolyte level. In many of the modern station batteries, the jar containing the electrolyte is so large with the band between the high and low electrolyte level so wide that normal evaporation which would require periodic watering of all cells takes several years to occur. However, because loss of electrolyte due to cracks in the jar, overcharging of the station battery, or other unforeseen events can cause rapid loss of electrolyte; the shorter maximum maintenance intervals for checking the electrolyte level are required. A low level of electrolyte in a VLA battery cell which exposes the tops of the plates can cause the exposed portion of the plates to accelerated sulfation resulting in loss of cell capacity. Also, in a VLA battery where the electrolyte level goes below the end of the cell withdrawal tube or filling funnel, gasses can exit the cell by the tube instead of the flame arrester and present an explosion hazard.

What are the parameters that can be evaluated in Tables 1-4(a) and 1-4(b)?

The most common parameter that is periodically trended and evaluated by industry today to verify that the station battery can perform as manufactured is internal ohmic cell/unit measurements.

In the mid-1990s, several large and small utilities began developing maintenance and testing programs for Protection System station batteries using a condition based maintenance approach of trending internal ohmic measurements to each station battery cell's baseline value. Battery owners use the data collected from this maintenance activity to determine (1) when a station battery requires a capacity test (instead of performing a capacity test on a predetermined, prescribed interval), (2) when an individual cell or battery unit should be replaced, or (3) based on the analysis of the trended data, if the station battery should be replaced without performing a capacity test.

Other examples of measurable parameters that can be periodically trended and evaluated for lead acid batteries are cell voltage, float current, connection resistance. However, periodically trending and evaluating cell/unit Ohmic measurements are the most common battery/cell parameters that are evaluated by industry to verify a lead acid battery string can perform as manufactured.

Why does it appear that there are two maintenance activities in Table 1-4(b) (for VRLA batteries) that appear to be the same activity and have the same maximum maintenance interval?

There are two different and distinct reasons for doing almost the same maintenance activity at the same interval for valve-regulated lead-acid (VRLA) batteries. The first similar activity for VRLA batteries (Table 1-4(b)) that has the same maximum maintenance interval is to "measure battery cell/unit internal ohmic values." Part of the reason for this activity is because the visual inspection of the cell condition is unavailable for VRLA batteries. Besides the requirement to

measure the internal ohmic measurements of VRLA batteries to determine the internal health of the cell, the maximum maintenance interval for this activity is significantly shorter than the interval for vented lead-acid (VLA) due to some unique failure modes for VRLA batteries. Some of the potential problems that VRLA batteries are susceptible to that do not affect VLA batteries are thermal runaway, cell dry-out, and cell reversal when one cell has a very low capacity.

The other similar activity listed in Table 1-4(b) is "…verify that the station battery can perform as manufactured by evaluating the measured cell/unit measurements indicative of battery performance (e.g. internal ohmic values) against the station battery baseline." This activity allows an owner the option to choose between this activity with its much shorter maximum maintenance interval or the longer maximum maintenance interval for the maintenance activity to "Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank."

For VRLA batteries, there are two drivers for internal ohmic readings. The first driver is for a means to trend battery life. Trending against the baseline of VRLA cells in a battery string is essential to determine the approximate state of health of the battery. Ohmic measurement testing may be used as the mechanism for measuring the battery cells. If all the cells in the string exhibit a consistent trend line and that trend line has not risen above a specific deviation (e.g. 30%) over baseline for impedance tests or below baseline for conductance tests, then a judgment can be made that the battery is still in a reasonably good state of health and able to 'perform as manufactured.' It is essential that the specific deviation mentioned above is based on data (test or otherwise) that correlates the ohmic readings for a specific battery/tester combination to the health of the battery. This is the intent of the "perform **as** manufactured six-month test" at Row 4 on Table 1-4b.

The second big driver is VRLA batteries tendency for thermal runaway. This is the intent of the "thermal runaway test" at Row 2 on Table 1-4b. In order to detect a cell in thermal runaway, you need not necessarily have a formal trending program. When a single cell/unit changes significantly or significantly varies from the other cells (e.g. a doubling of resistance/impedance or a 50% decrease in conductance), there is a high probability that the cell/unit/string needs to be replaced as soon as possible. In other words, if the battery is 10 years old and all the cells have approached a significant change in ohmic values over baseline, then you have a battery which is approaching end of life. You need to get ready to buy a new battery, but you do not have to worry about an impending catastrophic failure. On the other hand, if the battery is five years old and you have one cell that has a markedly different ohmic reading than all the other cells, then you need to be worried that this cell is susceptible to thermal runaway. If the float (charging) current has risen significantly and the ohmic measurement has increased/decreased as described above then concern of catastrophic failure should trigger attention for corrective action.

If an entity elects to use a capacity test rather than a cell ohmic value trending program, this does not eliminate the need to be concerned about thermal runaway – the entity still needs to do the six-month readings and look for cells which are outliers in the string but they need not trend results against the factory/as new baseline. Some entities will not mind the extra administrative burden of having the ongoing trending program against baseline - others would rather just do

the capacity test and not have to trend the data against baseline. Nonetheless, all entities must look for ohmic outliers on a six-month basis.

It is possible to accomplish both tasks listed (trend testing for capability and testing for thermal runaway candidates) with the very same ohmic test. It becomes an analysis exercise of watching the trend from baselines and watching for the oblique cell measurement.

In table 1-4(f) (Exclusions for Protection System Station dc Supply Monitoring Devices and Systems), must all component attributes listed in the table be met before an exclusion can be granted for a maintenance activity?

Table 1-4(f) was created by the drafting team to allow Protection System dc supply owners to obtain exclusions from periodic maintenance activities by using monitoring devices. The basis of the exclusions granted in the table is that the monitoring devices must incorporate the monitoring capability of microprocessor based components which perform continuous self-monitoring. For failure of the microprocessor device used in dc supply monitoring, the self-checking routine in the microprocessor must generate an alarm which will be reported within 24 hours of device failure to a location where corrective action can be initiated.

Table 1-4(f) lists 8 component attributes along with a specific periodic maintenance activity associated with each of the 8 attributes listed. If an owner of a station dc supply wants to be excluded from periodically performing one of the 8 maintenance activities listed in table 1-4(f), the owner must have evidence that the monitoring and alarming component attributes associated with the excluded maintenance activity are met by the self-checking microprocessor based device with the specific component attribute listed in the table 1-4(f).

For example if an owner of a VLA station battery does not want to “verify station dc supply voltage” every “4 calendar months” (see table 1-4(a)), the owner can install a monitoring and alarming device “with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure” and “no periodic verification of station dc supply voltage is required” (see table 1-4(f) first row). However, if for the same Protection System discussed above, the owner does not install “electrolyte level monitoring and alarming in every cell” and “unintentional dc ground monitoring and alarming” (see second and third rows of table 1-4(f)), the owner will have to “inspect electrolyte level and for unintentional grounds” every “4 calendar months” (see table 1-4(a)).

15.5 Associated communications equipment (Table 1-2)

The equipment used for tripping in a communications-assisted trip scheme is a vital piece of the trip circuit. Remote action causing a local trip can be thought of as another parallel trip path to the trip coil that must be tested. Besides the trip output and wiring to the trip coil(s), there is also a communications medium that must be maintained. Newer technologies now exist that achieve communications-assisted tripping without the conventional wiring practices of older technology. For example, older technologies may have included Frequency Shift Key methods. This technology requires that guard and trip levels be maintained. The actual tripping path(s) to the trip coil(s) may be tested as a parallel trip path within the dc control circuitry tests. Emerging technologies transfer digital information over a variety of carrier mediums that are then

interpreted locally as trip signals. The requirements apply to the communicated signal needed for the proper operation of the protective relay trip logic or scheme. Therefore, this standard is applied to equipment used to convey both trip signals (permissive or direct) and block signals.

It was the intent of this standard to require that a test be performed on any communications-assisted trip scheme, regardless of the vintage of technology. The essential element is that the tripping (or blocking) occurs locally when the remote action has been asserted; or that the tripping (or blocking) occurs remotely when the local action is asserted. Note that the required testing can still be done within the concept of testing by overlapping segments. Associated communications equipment can be (but is not limited to) testing at other times and different frequencies as the protective relays, the individual trip paths and the affected circuit interrupting devices.

Some newer installations utilize digital signals over fiber-optics from the protective relays in the control house to the circuit interrupting device in the yard. This method of tripping the circuit breaker, even though it might be considered communications, must be maintained per the dc control circuitry maintenance requirements.

15.5.1 Frequently Asked Questions:

What are some examples of mechanisms to check communications equipment functioning?

For unmonitored Protection Systems, various types of communications systems will have different facilities for on-site integrity checking to be performed at least every four months during a substation visit. Some examples are, but not limited to:

- On-off power-line carrier systems can be checked by performing a manual carrier keying test between the line terminals, or carrier check-back test from one terminal.
- Systems which use frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be checked by observing for a loss-of-guard indication or alarm. For frequency-shift power-line carrier systems, the guard signal level meter can also be checked.
- Hard-wired pilot wire line Protection Systems typically have pilot-wire monitoring relays that give an alarm indication for a pilot wire ground or open pilot wire circuit loop.
- Digital communications systems typically have a data reception indicator or data error indicator (based on loss of signal, bit error rate, or frame error checking).

For monitored Protection Systems, various types of communications systems will have different facilities for monitoring the presence of the communications channel, and activating alarms that can be monitored remotely. Some examples are, but not limited to:

- On-off power-line carrier systems can be shown to be operational by automated periodic power-line carrier check-back tests with remote alarming of failures.
- Systems which use a frequency-shift communications with a continuous guard signal (over a telephone circuit, analog microwave system, etc.) can be remotely monitored with a loss-of-guard alarm or low signal level alarm.
- Hard-wired pilot wire line Protection Systems can be monitored by remote alarming of pilot-wire monitoring relays.
- Digital communications systems can activate remotely monitored alarms for data reception loss or data error indications.
- Systems can be queried for the data error rates.

For the highest degree of monitoring of Protection Systems, the communications system must monitor all aspects of the performance and quality of the channel that show it meets the design performance criteria, including monitoring of the channel interface to protective relays.

- In many communications systems signal quality measurements, including signal-to-noise ratio, received signal level, reflected transmitter power or standing wave ratio, propagation delay, and data error rates are compared to alarm limits. These alarms are connected for remote monitoring.
- Alarms for inadequate performance are remotely monitored at all times, and the alarm communications system to the remote monitoring site must itself be continuously monitored to assure that the actual alarm status at the communications equipment location is continuously being reflected at the remote monitoring site.

What is needed for the four-month inspection of communications-assisted trip scheme equipment?

The four-month inspection applies to unmonitored equipment. An example of compliance with this requirement might be, but is not limited to:

With each site visit, check that the equipment is free from alarms; check any metered signal levels, and that power is still applied. While this might be explicit for a particular type of equipment (i.e., FSK equipment), the concept should be that the entity verify that the communications equipment that is used in a Protection System is operable through a cursory inspection and site visit. This site visit can be eliminated on this particular example if the FSK equipment had a monitored alarm on Loss of Guard. Blocking carrier systems with auto checkbacks will present an alarm when the channel fails allowing a visual indication. With no auto checkback, the channel integrity will need to be verified by a manual checkback or a two ended signal check. This check could also be eliminated by bring the auto checkback failure alarm to the monitored central location.

Does a fiber optic I/O scheme used for breaker tripping or control within a station, for example - transmitting a trip signal or control logic between the control house and the breaker control cabinet, constitute a communications system?

This equipment is presently classified as being part of the Protection System control circuitry and tested per the portions of Table 1 applicable to "Protection System Control Circuitry", rather than those portions of the table applicable to communications equipment.

What is meant by "Channel" and "Communications Systems" in Table 1-2?

The transmission of logic or data from a relay in one station to a relay in another station for use in a pilot relay scheme will require a communications system of some sort. Typical relay communications systems use fiber optics, leased audio channels, power line carrier, and microwave. The overall communications system includes the channel and the associated communications equipment.

This standard refers to the "channel" as the medium between the transmitters and receivers in the relay panels such as a leased audio or digital communications circuit, power line and power line carrier auxiliary equipment, and fiber. The dividing line between the channel and the associated communications equipment is different for each type of media.

Examples of the Channel:

- Power Line Carrier (PLC) - The PLC channel starts and ends at the PLC transmitter and receiver output unless there is an internal hybrid. The channel includes the external hybrids, tuners, wave traps and the power line itself.
- Microwave –The channel includes the microwave multiplexers, radios, antennae and associated auxiliary equipment. The audio tone and digital transmitters and receivers in the relay panel are the associated communications equipment.
- Digital/Audio Circuit – The channel includes the equipment within and between the substations. The associated communications equipment includes the relay panel transmitters and receivers and the interface equipment in the relays.

- Fiber Optic – The channel starts at the fiber optic connectors on the fiber distribution panel at the local station and goes to the fiber optic distribution panel at the remote substation. The jumpers that connect the relaying equipment to the fiber distribution panel and any optical-electrical signal format converters are the associated communications equipment

Figure 1-2, A-1 and A-2 at the end of this document show good examples of the communications channel and the associated communications equipment.

In Table 1-2, the Maintenance Activities section of the Protection System Communications Equipment and Channels refers to the quality of the channel meeting "performance criteria." What is meant by performance criteria?

Protection System communications channels must have a means of determining if the channel and communications equipment is operating normally. If the channel is not operating normally, an alarm will be indicated. For unmonitored systems, this alarm will probably be on the panel. For monitored systems, the alarm will be transmitted to a remote location.

Each entity will have established a nominal performance level for each Protection System communications channel that is consistent with proper functioning of the Protection System. If that level of nominal performance is not being met, the system will go into alarm. Following are some examples of Protection System communications channel performance measuring:

- For direct transfer trip using a frequency shift power line carrier channel, a guard level monitor is part of the equipment. A normal receive level is established when the system is calibrated and if the signal level drops below an established level, the system will indicate an alarm.
- An on-off blocking signal over power line carrier is used for directional comparison blocking schemes on transmission lines. During a Fault, block logic is sent to the remote relays by turning on a local transmitter and sending the signal over the power line to a receiver at the remote end. This signal is normally off so continuous levels cannot be checked. These schemes use check-back testing to determine channel performance. A predetermined signal sequence is sent to the remote end and the remote end decodes this signal and sends a signal sequence back. If the sending end receives the correct information from the remote terminal, the test passes and no alarm is indicated. Full power and reduced power tests are typically run. Power levels for these tests are determined at the time of calibration.
- Pilot wire relay systems use a hardwire communications circuit to communicate between the local and remote ends of the protective zone. This circuit is monitored by circulating a dc current between the relay systems. A typical level may be 1 mA. If the level drops below the setting of the alarm monitor, the system will indicate an alarm.
- Modern digital relay systems use data communications to transmit relay information to the remote end relays. An example of this is a line current differential scheme commonly used on transmission lines. The protective relays communicate current magnitude and phase information over the communications path to determine if the Fault is located in the protective zone. Quantities such as digital packet loss, bit error rate and channel delay are monitored to determine the quality of the channel. These limits are determined and

set during relay commissioning. Once set, any channel quality problems that fall outside the set levels will indicate an alarm.

The previous examples show how some protective relay communications channels can be monitored and how the channel performance can be compared to performance criteria established by the entity. This standard does not state what the performance criteria will be; it just requires that the entity establish nominal criteria so Protection System channel monitoring can be performed.

How is the performance criteria of Protection System communications equipment involved in the maintenance program?

An entity determines the acceptable performance criteria, depending on the technology implemented. If the communications channel performance of a Protection System varies from the pre-determined performance criteria for that system, then these results should be investigated and resolved.

How do I verify the A/D converters of microprocessor-based relays?

There are a variety of ways to do this. Two examples would be: using values gathered via data communications and automatically comparing these values with values from other sources, or using groupings of other measurements (such as vector summation of bus feeder currents) for comparison. Many other methods are possible.

15.6 Alarms (Table 2)

In addition to the tables of maintenance for the components of a Protection System, there is an additional table added for alarms. This additional table was added for clarity. This enabled the common alarm attributes to be consolidated into a single spot, and, thus, make it easier to read the Tables 1-1 through 1-5, Table 3, and Table 4. The alarms need to arrive at a site wherein a corrective action can be initiated. This could be a control room, operations center, etc. The alarming mechanism can be a standard alarming system or an auto-polling system; the only requirement is that the alarm be brought to the action-site within 24 hours. This effectively makes manned-stations equivalent to monitored stations. The alarm of a monitored point (for example a monitored trip path with a lamp) in a manned-station now makes that monitored point eligible for monitored status. Obviously, these same rules apply to a non-manned-station, which is that if the monitored point has an alarm that is auto-reported to the operations center (for example) within 24 hours, then it too is considered monitored.

15.6.1 Frequently Asked Questions:

Why are there activities defined for varying degrees of monitoring a Protection System component when that level of technology may not yet be available?

There may already be some equipment available that is capable of meeting the highest levels of monitoring criteria listed in the Tables. However, even if there is no equipment available today that can meet this level of monitoring the standard establishes the necessary requirements for when such equipment becomes available. By creating a roadmap for development, this provision makes the standard technology neutral. The Standard Drafting Team wants to avoid the need to revise the standard in a few years to accommodate technology advances that may be coming to the industry.

Does a fail-safe "form b" contact that is alarmed to a 24/7 operation center classify as an alarm path with monitoring?

If the fail-safe "form-b" contact that is alarmed to a 24/7 operation center causes the alarm to activate for failure of any portion of the alarming path from the alarm origin to the 24/7 operations center, then this can be classified as an alarm path with monitoring.

15.7 Distributed UFLS and Distributed UVLS Systems (Table 3)

Distributed UFLS and distributed UVLS systems have their maintenance activities documented in Table 3 due to their distributed nature allowing reduced maintenance activities and extended maximum maintenance intervals. Relays have the same maintenance activities and intervals as Table 1-1. Voltage and current-sensing devices have the same maintenance activity and interval as Table 1-3. DC systems need only have their voltage read at the relay every 12 years. Control circuits have the following maintenance activities every 12 years:

- Verify the trip path between the relay and lock-out and/or auxiliary tripping device(s).
- Verify operation of any lock-out and/or auxiliary tripping device(s) used in the trip circuit.
- No verification of trip path required between the lock-out (and/or auxiliary tripping device) and the non-BES interrupting device.
- No verification of trip path required between the relay and trip coil for circuits that have no lock-out and/or auxiliary tripping device(s).
- No verification of trip coil required.

No maintenance activity is required for associated communication systems for distributed UFLS and distributed UVLS schemes.

Non-BES interrupting devices that participate in a distributed UFLS or distributed UVLS scheme are excluded from the tripping requirement, and part of the control circuit test requirement; however, the part of the trip path control circuitry between the Load-Shed relay and lock-out or auxiliary tripping relay must be tested at least once every 12 years. In the case where there is no lock-out or auxiliary tripping relay used in a distributed UFLS or UVLS scheme which is not part of the BES, there is no control circuit test requirement. There are many circuit interrupting devices in the distribution system that will be operating for any given under-frequency event that requires tripping for that event. A failure in the tripping action of a single distributed system circuit breaker (or non-BES equipment interruption device) will be far less significant than, for example, any single transmission Protection System failure, such as a failure of a bus differential lock-out relay. While many failures of these distributed system circuit breakers (or non-BES equipment interruption device) could add up to be significant, it is also believed that many circuit breakers are operated often on just Fault clearing duty; and, therefore, these circuit breakers are operated at least as frequently as any requirements that appear in this standard.

There are times when a Protection System component will be used on a BES device, as well as a non-BES device, such as a battery bank that serves both a BES circuit breaker and a non-BES interrupting device used for UFLS. In such a case, the battery bank (or other Protection System component) will be subject to the Tables of the standard because it is used for the BES.

15.7.1 Frequently Asked Questions:

The standard reaches further into the distribution system than we would like for UFLS and UVLS

While UFLS and UVLS equipment are located on the distribution network, their job is to protect the Bulk Electric System. This is not beyond the scope of NERC's 215 authority.

FPA section 215(a) definitions section defines bulk power system as: "(A) facilities and control Systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)." That definition, then, is limited by a later statement which adds the term bulk power system "…does not include facilities used in the local distribution of electric energy." Also, Section 215 also covers users, owners, and operators of bulk power Facilities.

UFLS and UVLS (when the UVLS is installed to prevent system voltage collapse or voltage instability for BES reliability) are not "used in the local distribution of electric energy," despite their location on local distribution networks. Further, if UFLS/UVLS Facilities were not covered by the reliability standards, then in order to protect the integrity of the BES during under-frequency or under-voltage events, that Load would have to be shed at the Transmission bus to ensure the Load-generation balance and voltage stability is maintained on the BES.

15.8 Automatic Reclosing (Table 4)

Please see the document referenced in Section F of PRC-005-3, "Considerations for Maintenance and Testing of Autoreclosing Schemes — November 2012", for a discussion of Automatic Reclosing as addressed in PRC-005-3.

15.8.1 Frequently-asked Questions

Automatic Reclosing is a control, not a protective function; why then is Automatic Reclosing maintenance included in the Protection System Maintenance Program (PSMP)?

Automatic Reclosing is a control function. The standard's title 'Protection System and Automatic Reclosing Maintenance' clearly distinguishes (separates) the Automatic Reclosing from the Protection System. Automatic Reclosing is included in the PSMP because it is a more pragmatic approach as compared to creating a parallel and essentially identical 'Control System Maintenance Program' for the two Automatic Reclosing component types.

When do I need to have the initial maintenance of Automatic Reclosing Components completed upon change of the largest BES generating unit in the BA/RSG?

The maintenance interval, for newly identified Automatic Reclosing Components, starts when a change in the largest BES generating unit is determined by the BA/RSG. The first maintenance records for newly identified Automatic Reclosing Components should be dated no later than the maximum maintenance interval after the identification date. The maximum maintenance intervals for each newly identified Component are defined in Table 4. No activities or records are required prior to the date of identification.

Our maintenance practice consists of initiating the Automatic Reclosing relay and confirming the breaker closes properly and the close signal is released. This practice verifies the control circuitry associated with Automatic Reclosing. Do you agree?"

The described task partially verifies the control circuit maintenance activity. To meet the control circuit maintenance activity, responsible entities need to verify, *upon initiation*, that the reclosing relay does not issue a *premature closing command*. As noted on page 12 of the SAMS/SPCS report, the concern being addressed within the standard is premature auto reclosing that has the potential to cause generating unit or plant instability. Reclosing applications have many variations, responsible entities will need to verify the applicability of associated supervision/conditional logic and the reclosing relay operation; then verify the conditional logic or that the reclosing relay performs in a manner that does not result in a *premature closing command* being issued.

Some examples of conditions which can result in a premature closing command are: an improper supervision or conditional logic input which provides a false state and allows the reclosing relay to issue an improper close command based on incorrect conditions (i.e. voltage supervision, equipment status, sync window verification); timers utilized for closing actuation or reclosing arming/disarming circuitry which could allow the reclosing relay to issue an improper close command; a reclosing relay output contact failure which could result in a made-up-close condition / failure-to-release condition.

Why was a close-in three phase fault present for twice the normal clearing time chosen for the Automatic Reclosing exclusion? It exceeds TPL requirements and ignores the breaker closing time in a trip-close-trip sequence, thus making the exclusion harder to attain.

This condition represents a situation where a close signal is issued with no time delay or with less time delay than is intended, such as if a reclosing contact is welded closed. This failure mode can result in a minimum trip-close-trip sequence with the two faults cleared in primary protection operating time, and the open time between faults equal to the breaker closing cycle time. The sequence for this failure mode results in system impact equivalent to a high-speed autoreclosing sequence with no delay added in the autoreclosing logic. It represents a failure mode which must be avoided because it exceeds TPL requirements.

Do we have to test the various breaker closing circuit interlocks and controls such as anti-pump?

These components are not specifically addressed within Table 4, and need not be individually tested. They are indirectly verified by performing the Automatic Reclosing control circuitry verification as established in Table 4.

For Automatic Reclosing that <u>is not</u> part of an RAS, do we have to close the circuit breaker periodically?

No. For this application, you need only to verify that the Automatic Reclosing, upon initiation, does not issue a premature closing command. This activity is concerned only with assuring that a premature close does not occur, and cause generating plant instability.

For Automatic Reclosing that <u>is</u> part of an RAS, do we have to close the circuit breaker periodically?

Yes. In this application, successful closing is a necessary portion of the RAS, and must be verified.

Why is maintenance of supervisory relays now included in PRC-005 for Automatic Reclosing?

Proper performance of supervising relays supports the reliability of the BES because some conditions can result in a premature closing command. An example of this would be an improper supervision or conditional logic input which provides a false state and allows the reclosing relay to issue an improper close command based on incorrect conditions (i.e. voltage supervision, sync window verification)

My reclosing circuitry contains the following inputs listed below; what supervising relays would need to tested per PRC-005?

- 79/ON – Supervisory contact which turns Automatic reclosing ON or OFF
- 52 – Supervisory contact which provides breaker indication ("b" contact)
- 86 - Supervisory contact from a lockout relay
- 79 – Supervisory contact from a reclosing relay
- 25 – Supervisory contact from a sync-check relay
- 27 or 59 – Supervisory contact from a undervoltage of overvoltage relay

Supervising Relays are defined in this standard as "relay(s) that perform voltage and/or sync check functions that enables or disables operation of the reclosing relay." The 79/ON, 52, and 86 would not need to be included. However, the 79, 25, and 27 or 59 would be included because they are supervisory devices that are either associated with autoreclosing, sync-checks, and/or voltage.

The sync check and voltage check functions are part of my microprocessor reclosing relay. Are there any test requirements for these internal supervisory functions?

A microprocessor reclosing relay that is using internal sync check or voltage check supervisory functions is a combinational reclosing and supervisory relay (i.e. 79/25). The maintenance activities for both a reclosing relay and supervisory relay would apply. The voltage sensing devices providing input to a combinational reclosing and supervisory relay would require the activities in Table 4-3.

Is it necessary to verify the close signal operates the breaker?

Only when the control circuitry associated with automatic reclosing is a part of a RAS, then all paths that are essential for proper operation of the RAS must be verified, per table 4-2(b).

15.9 Sudden Pressure Relaying (Table 5)

Please see the document referenced in Section F of PRC-005-4, "Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities – December 2013", for a discussion of Sudden Pressure Relaying as addressed in PRC-005-4.

15.9.1 Frequently Asked Questions:

How do I verify the pressure or flow sensing mechanism is operable?

Maintenance activities for the fault pressure relay associated with Sudden Pressure Relaying in PRC-005-4 are intended to verify that the pressure and/or flow sensing mechanism are functioning correctly. Beyond this, PRC-005-4 requires no calibration (adjusting the operating threshold or measurement accuracy of a measuring element to meet the intended performance requirement) or testing (applying signals to a component to observe functional performance or output behavior, or to diagnose problems) activities. For example, some designs of flow sensing mechanisms allow the operation of a test switch to actuate the limit switch of the flow sensing mechanism. Operation of this test switch and verification of the flow sensing mechanism would meet the requirements of the maintenance activity. Another example involves a gas pressure sensing mechanism which is isolated by a test plug. Removal of the plug and verification of the bellows mechanism would meet the requirements of the maintenance activity.

Why the 6-year maximum maintenance interval for fault pressure relays?

The SDT established the six-year maintenance interval for fault pressure relays (see Table 5, PRC-005-4) based on the recommendation of the System Protection and Control Subcommittee (SPCS). The technical experts of the SPCS were tasked with developing the technical documents to:

i. Describe the devices and functions (to include sudden pressure relays which trip for fault conditions) that should address FERC's concern; and

ii. Propose minimum maintenance activities for such devices and maximum maintenance intervals, including the technical basis for each.

Excerpt from the SPCS technical report: "In order to determine present industry practices related to sudden pressure relay maintenance, the SPCS conducted a survey of Transmission Owners and Generator Owners in all eight Regions requesting information related to their maintenance practices. The SPCS received responses from 75 Transmission Owners and 109 Generator Owners. Note that, for the purpose of the survey, sudden pressure relays included the following: the "sudden pressure relay" (SPR) originally manufactured by Westinghouse, the "rapid pressure rise relay" (RPR) manufactured by Qualitrol, and a variety of Buchholz relays.

Table 2 provides a summary of the results of the responses:

Table 2: Sudden Pressure Relay Maintenance Practices – Survey Results

	Transmission Owner	Generator Owner
Number of responding owners that trip with Sudden Pressure Relays:	67	84
Percentage of responding owners who trip that have a Maintenance Program:	75%	78%
Percentage of maintenance programs that include testing the pressure actuator:	81%	77%

Average Maintenance interval reported:	5.9 years	4.9 years

Additionally, in order to validate the information noted above, the SPCS contacted the following entities for their feedback: the IEEE Power System Relaying Committee, the IEEE Transformer Committee, the Doble Transformer Committee, the NATF System Protection Practices Group, and the EPRI Generator Owner/Operator Technical Focus Group. All of these organizations indicated the results of the SPCS survey are consistent with their respective experiences.

The SPCS discussed the potential difference between the recommended intervals for fault pressure relaying and intervals for transformer maintenance. The SPCS developed the recommended intervals for fault pressure relaying by comparing fault pressure relaying to Protection System Components with similar physical attributes. The SPCS recognized that these intervals may be shorter than some existing or future transformer maintenance intervals, but believed it to be more important to base intervals for fault pressure relaying on similar Protection System Components than transformer maintenance intervals.

The maintenance interval for fault pressure relays can be extended by utilizing performance-based maintenance thereby allowing entities that have maintenance intervals for transformers in excess of six years, to align them.

Sudden Pressure Relaying control circuitry is now specifically mentioned in the maintenance tables. Do we have to trip our circuit breaker specifically from the trip output of the sudden pressure relay?

No. Verification may be by breaker tripping, but may be verified in overlapping segments with the Protection System control circuitry.

Can we use Performance Based Maintenance for fault pressure relays?

Yes. Performance Based Maintenance is applicable to fault pressure relays.

15.10 Examples of Evidence of Compliance

To comply with the requirements of this standard, an entity will have to document and save evidence. The evidence can be of many different forms. The Standard Drafting Team recognizes that there are concurrent evidence requirements of other NERC standards that could, at times, fulfill evidence requirements of this standard.

15.10.1 Frequently Asked Questions:

What forms of evidence are acceptable?

Acceptable forms of evidence, as relevant for the requirement being documented include, but are not limited to:

- Process documents or plans
- Data (such as relay settings sheets, photos, SCADA, and test records)
- Database lists, records and/or screen shots that demonstrate compliance information
- Prints, diagrams and/or schematics
- Maintenance records

- Logs (operator, substation, and other types of log)
- Inspection forms
- Mail, memos, or email proving the required information was exchanged, coordinated, submitted or received
- Check-off forms (paper or electronic)
- Any record that demonstrates that the maintenance activity was known, accounted for, and/or performed.

If I replace a failed Protection System component with another component, what testing do I need to perform on the new component?

In order to reset the Table 1 maintenance interval for the replacement component, all relevant Table 1 activities for the component should be performed.

I have evidence to show compliance for PRC-016 ("Special Protection System Misoperation"). Can I also use it to show compliance for this Standard, PRC-005-4?

Maintaining evidence for operation of Remedial Action Schemes could concurrently be utilized as proof of the operation of the associated trip coil (provided one can be certain of the trip coil involved). Thus, the reporting requirements that one may have to do for the Misoperation of a Special Protection Scheme under PRC-016 could work for the activity tracking requirements under this PRC-005-4.

I maintain Disturbance records which show Protection System operations. Can I use these records to show compliance?

These records can be concurrently utilized as dc trip path verifications, to the degree that they demonstrate the proper function of that dc trip path.

I maintain test reports on some of my Protection System components. Can I use these test reports to show that I have verified a maintenance activity?

Yes.

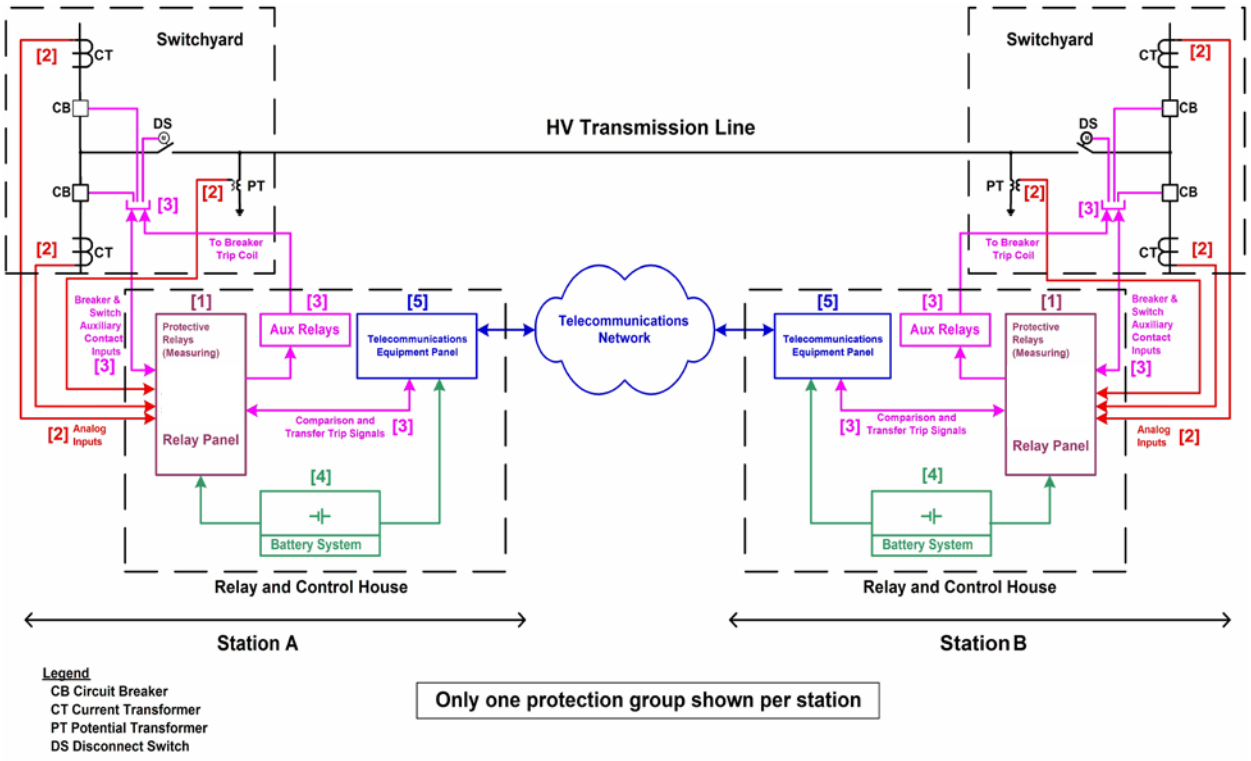
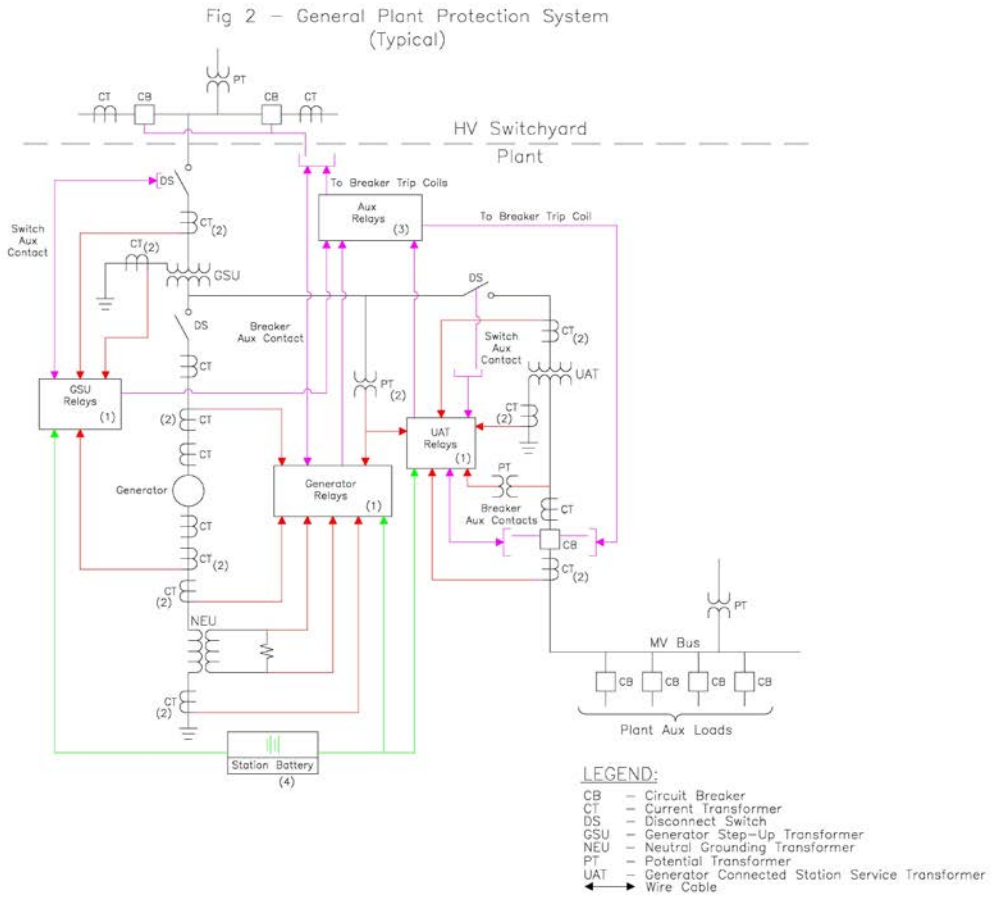
Figures

Figure 1: Typical Transmission System



For information on components, see ***Figure 1 & 2 Legend – components of Protection Systems***

Figure 2: Typical Generation System



Note: Figure 2 may show elements that are not included within PRC-005-2, and also may not be all-inclusive; see the Applicability section of the standard for specifics.

For information on components, see ***Figure 1 & 2 Legend – components of Protection Systems***

Figure 1 & 2 Legend – Components of Protection Systems

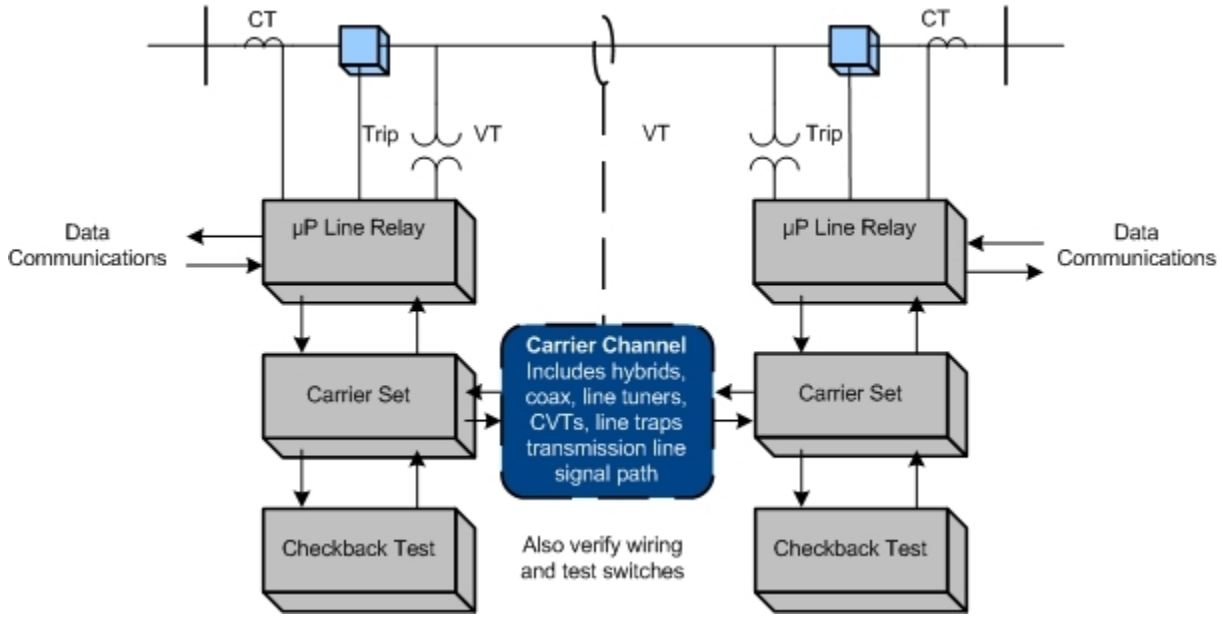
Number in Figure	Component of Protection System	Includes	Excludes
1	Protective relays which respond to electrical quantities	All protective relays that use current and/or voltage inputs from current & voltage sensors and that trip the 86, 94 or trip coil.	Devices that use non-electrical methods of operation including thermal, pressure, gas accumulation, and vibration. Any ancillary equipment not specified in the definition of Protection Systems. Control and/or monitoring equipment that is not a part of the automatic tripping action of the Protection System
2	Voltage and current sensing devices providing inputs to protective relays	The signals from the voltage & current sensing devices to the protective relay input.	Voltage & current sensing devices that are not a part of the Protection System, including, metering systems and data acquisition systems.
3	Control circuitry associated with protective functions	All control wiring (or other medium for conveying trip signals) associated with the tripping action of 86 devices, 94 devices or trip coils (from all parallel trip paths). This would include fiber-optic systems that carry a trip signal as well as hard-wired systems that carry trip current.	Closing circuits, SCADA circuits, other devices in control scheme not passing trip current
4	Station dc supply	Batteries and battery chargers and any control power system which has the function of supplying power to the protective relays, associated trip circuits and trip coils.	Any power supplies that are not used to power protective relays or their associated trip circuits and trip coils.
5	Communications systems necessary for correct operation of protective functions	Tele-protection equipment used to convey specific information, in the form of analog or digital signals, necessary for the correct operation of protective functions.	Any communications equipment that is not used to convey information necessary for the correct operation of protective functions.

Additional information can be found in References

Appendix A

The following illustrates the concept of overlapping verifications and tests as summarized in Section 10 of the paper. As an example, Figure A-1 shows protection for a critical transmission line by carrier blocking directional comparison pilot relaying. The goal is to verify the ability of the entire two-terminal pilot protection scheme to protect for line Faults, and to avoid over-tripping for Faults external to the transmission line zone of protection bounded by the current transformer locations.

Figure A-1



In this example (Figure A1), verification takes advantage of the self-monitoring features of microprocessor multifunction line relays at each end of the line. For each of the line relays themselves, the example assumes that the user has the following arrangements in place:

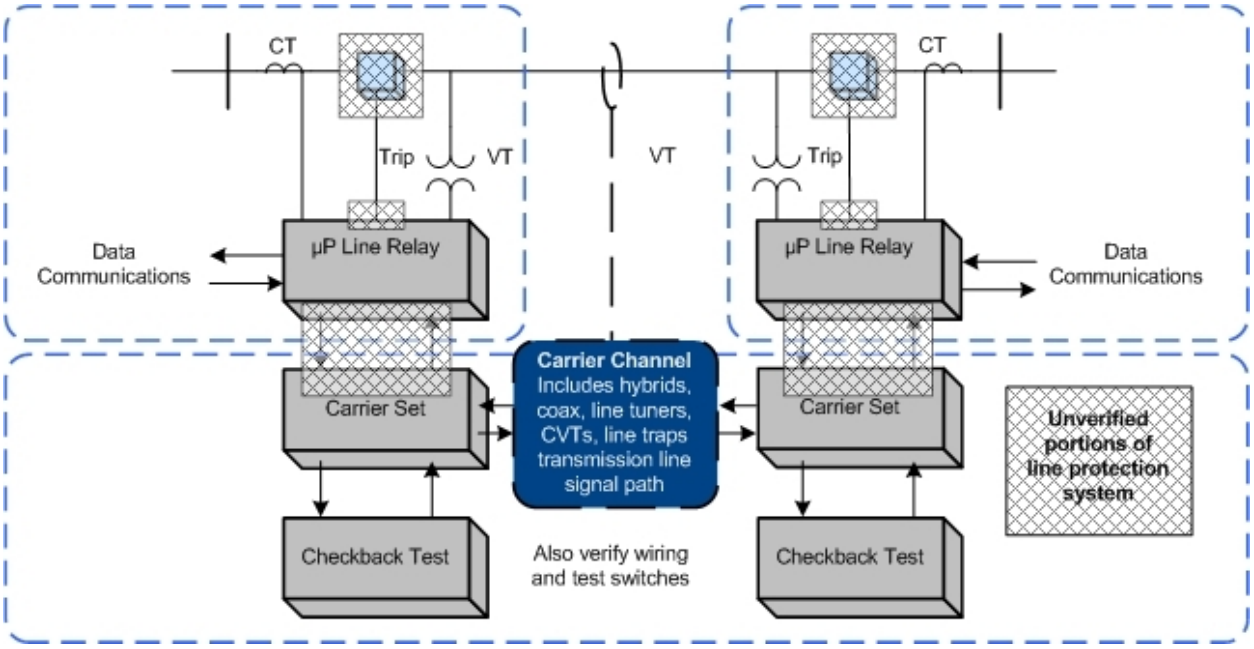
1. The relay has a data communications port that can be accessed from remote locations.
2. The relay has internal self-monitoring programs and functions that report failures of internal electronics, via communications messages or alarm contacts to SCADA.
3. The relays report loss of dc power, and the relays themselves or external monitors report the state of the dc battery supply.
4. The CT and PT inputs to the relays are used for continuous calculation of metered values of volts, amperes, plus Watts and VARs on the line. These metered values are reported by data communications. For maintenance, the user elects to compare these readings to those of other relays, meters, or DFRs. The other readings may be from redundant relaying or measurement systems or they may be derived from values in other protection zones. Comparison with other such readings to within required relaying accuracy verifies voltage & current sensing devices, wiring, and analog signal input processing of the relays. One

effective way to do this is to utilize the relay metered values directly in SCADA, where they can be compared with other references or state estimator values.

5. Breaker status indication from auxiliary contacts is verified in the same way as in (2). Status indications must be consistent with the flow or absence of current.
6. Continuity of the breaker trip circuit from dc bus through the trip coil is monitored by the relay and reported via communications.
7. Correct operation of the on-off carrier channel is also critical to security of the Protection System, so each carrier set has a connected or integrated automatic checkback test unit. The automatic checkback test runs several times a day. Newer carrier sets with integrated checkback testing check for received signal level and report abnormal channel attenuation or noise, even if the problem is not severe enough to completely disable the channel.

These monitoring activities plus the check-back test comprise automatic verification of all the Protection System elements that experience tells us are the most prone to fail. But, does this comprise a complete verification?

Figure A-2



The dotted boxes of Figure A-2 show the sections of verification defined by the monitoring and verification practices just listed. These sections are not completely overlapping, and the shaded regions show elements that are not verified:

1. The continuity of trip coils is verified, but no means is provided for validating the ability of the circuit breaker to trip if the trip coil should be energized.

2. Within each line relay, all the microprocessors that participate in the trip decision have been verified by internal monitoring. However, the trip circuit is actually energized by the contacts of a small telephone-type "ice cube" relay within the line protective relay. The microprocessor energizes the coil of this ice cube relay through its output data port and a transistor driver circuit. There is no monitoring of the output port, driver circuit, ice cube relay, or contacts of that relay. These components are critical for tripping the circuit breaker for a Fault.
3. The check-back test of the carrier channel does not verify the connections between the relaying microprocessor internal decision programs and the carrier transmitter keying circuit or the carrier receiver output state. These connections include microprocessor I/O ports, electronic driver circuits, wiring, and sometimes telephone-type auxiliary relays.
4. The correct states of breaker and disconnect switch auxiliary contacts are monitored, but this does not confirm that the state change indication is correct when the breaker or switch opens.

A practical solution for (1) and (2) is to observe actual breaker tripping, with a specified maximum time interval between trip tests. Clearing of naturally-occurring Faults are demonstrations of operation that reset the time interval clock for testing of each breaker tripped in this way. If Faults do not occur, manual tripping of the breaker through the relay trip output via data communications to the relay microprocessor meets the requirement for periodic testing.

PRC-005-4 does not address breaker maintenance, and its Protection System test requirements can be met by energizing the trip circuit in a test mode (breaker disconnected) through the relay microprocessor. This can be done via a front-panel button command to the relay logic, or application of a simulated Fault with a relay test set. However, utilities have found that breakers often show problems during Protection System tests. It is recommended that Protection System verification include periodic testing of the actual tripping of connected circuit breakers.

Testing of the relay-carrier set interface in (3) requires that each relay key its transmitter, and that the other relay demonstrate reception of that blocking carrier. This can be observed from relay or DFR records during naturally occurring Faults, or by a manual test. If the checkback test sequence were incorporated in the relay logic, the carrier sets and carrier channel are then included in the overlapping segments monitored by the two relays, and the monitoring gap is completely eliminated.

Consideration of Directives

Project 2007-17.4 – PRC-005 Order 803 Directive

April 22, 2015

Project 2007-17.4 – PRC-005 Order 803 Directive		
Issue or Directive	**Source**	**Consideration of Issue or Directive**
In Order No. 803, FERC approved Standard PRC-005-3 and, in Paragraph 31, directed NERC to: "...direct that, pursuant to section 215(d)(5) of the FPA, NERC develop modifications to PRC-005-3 to include supervisory devices associated with auto-reclosing relay schemes to which the Reliability Standard applies. Further, we clarify that NERC's proposal regarding the scope of supervisory devices is an acceptable approach to satisfy the Commission directive. Specifically, NERC proposed in its NOPR comments, and we find acceptable, that the scope of the supervisory devices to be encompassed in the Reliability Standard are those providing voltage supervision, supervisory inputs associated with selective auto-reclosing, and sync-check relays that are part of a reclosing scheme covered by PRC-005-3."	FERC Order 803 approving Reliability Standard PRC-005-3, P Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance	The Protection System Maintenance and Testing Standard Drafting Team (PSMTSDT) proposed revision of the standard specific defined terms "Automatic Reclosing" and "Component Type" as follows: Automatic Reclosing – Includes the following Components: • Reclosing relay • Supervisory relay(s) – relay(s) that perform voltage and/or sync check functions that enables or disables operation of the reclosing relay • Voltage sensing devices associated with the supervisory relay(s) • Control circuitry associated with the reclosing relay or supervisory relay(s) Component Type –

Project 2007-17.4 – PRC-005 Order 803 Directive		
Issue or Directive	**Source**	**Consideration of Issue or Directive**
		• Any one of the five specific elements of a Protection System. • Any one of the two four specific elements of Automatic Reclosing. • Any one of the two specific elements of Sudden Pressure Relaying. The Rationales for "Automatic Relaying" and "Component Type" were also revised to reflect the proposed revisions to the defined terms above. Tables 4-1 and 4-2 were updated by adding "supervisory relay(s)" as appropriate. A new Table 4-3 was added to address maintenance activities and intervals for Automatic Reclosing with supervisory relays. No substantive revisions are being proposed for the Requirements of the standard. The only revisions to Requirements R1 and R3 included updating the Table numbering to reflect the addition of Table 4-3. The VSLs were updated to reflect the Requirement language for R1 and R3. All references to table numbering throughout the standard have also been corrected to reflect the addition of Table 4-3. This version of PRC-005 used PRC-005-5 developed under Project 2014-01 as the starting point for revisions to address the directive.

Implementation Plan

Project 2007-17.4 PRC-005 FERC Order No. 803 Directive PRC-005-6

Standards Involved

Approval:

- PRC-005-6 – Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance

Retirement:

- PRC-005-5 – Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance
- PRC-005-4 Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance
- PRC-005-3 (ii) Protection System and Automatic Reclosing Maintenance
- PRC-005-3 (i) Protection System and Automatic Reclosing Maintenance
- PRC-005-3 Protection System and Automatic Reclosing Maintenance
- PRC-005-2 (ii) Protection System Maintenance
- PRC-005-2 (i) Protection System Maintenance
- PRC-005-2 Protection System Maintenance
- PRC-005-1b – Transmission and Generation Protection System Maintenance and Testing
- PRC-008-0 – Implementation and Documentation of Underfrequency Load Shedding Equipment Maintenance Program
- PRC-011-0 – Undervoltage Load Shedding System Maintenance and Testing
- PRC-017-0 – Special Protection System Maintenance and Testing

Prerequisite Approvals:

N/A

Background:
In Order No. 803, FERC approved Standard PRC-005-3 and, in Paragraph 31, directed NERC to:

"...develop modifications to PRC-005-3 to include supervisory devices associated with auto-reclosing relay schemes to which the Reliability Standard applies. Further, we clarify that NERC's proposal regarding the scope of supervisory devices is an acceptable approach to satisfy the Commission directive. Specifically, NERC proposed in its NOPR comments, and we find acceptable, that the scope of the supervisory devices to be encompassed in the Reliability Standard are those providing voltage supervision, supervisory inputs associated with selective auto-reclosing, and sync-check relays that are part of a reclosing scheme covered by PRC-005-3."

This Implementation Plan adds:

- The implementation of changes relating to maintenance and testing of supervisory relays and associated voltage sensing devices related to Automatic Reclosing.
- The phased implementation approach included in the approved PRC-005-2 and proposed PRC-005-2(i) will remain as-is.
- This implementation schedule lays out the implementation timeline for the currently effective PRC-005-2 and proposed PRC-005-2(i), and combines the implementation plans for the approved PRC-005-3 and all subsequent pending PRC-005 versions (PRC-005-2(ii), PRC-005-3(i), PRC-005-3(ii), PRC-005-4 and PRC-005-5), making all versions from PRC-005-3 onwards effective on the same day PRC-005-6 becomes effective. The effective dates for the various phases specified in PRC -005-3 and each subsequent version of PRC-005 will align with the effective dates for those phases included in the PRC-005-6 Implementation Plan. For the pending versions that do not entail phased implementation, the versions will become effective on the date PRC-005-6 first becomes effective.
- Notwithstanding any order to the contrary, PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4 and PRC-005-5 will not become effective, and PRC-005-2 will remain in effect and not be retired until the effective date of the PRC-005-6 standard under this implementation plan.[1]

The Implementation Plan reflects consideration of the following:

1. The requirements set forth in the proposed standard, which carry forward requirements from PRC-005-2, PRC-005-2(i), PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4 and PRC-005-5, establish minimum maintenance activities for Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Types as well as the maximum allowable maintenance intervals for these maintenance activities.

[1] In jurisdictions where previous versions of PRC-005 have not yet become effective according to their implementation plans (even if approved by order), this implementation plan and the PRC-005-6 standard supersedes and replaces the implementation plans and standards for PRC-005-2(i), PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4, and PRC-005-5.

2. The maintenance activities established in the various PRC-005 versions may not be presently performed by some registered entities and the established maximum allowable intervals may be shorter than those currently in use by some entities. Therefore, registered entities may not be presently performing a maintenance activity or may be using longer intervals than the maximum allowable intervals established in the PRC-005 standards. For these registered entities, it is unrealistic to become immediately compliant with the new activities or intervals. Further, registered entities should be allowed to become compliant in such a way as to facilitate a continuing PRC-005 maintenance program. The registered entities that have previously been performing maintenance within the newly specified intervals may not have all the documentation needed to demonstrate compliance with all of the maintenance activities specified.
3. The implementation schedule set forth below carries forward the implementation schedules contained in PRC-005-2 and proposed PRC-005-2(i), and combines the implementation schedules for PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4 and PRC-005-5. In addition, the implementation schedule includes changes needed to address the addition of Automatic Reclosing supervisory relays and associated voltage sensing devices in PRC-005-6.

General Considerations:

Each Transmission Owner, Generator Owner, and Distribution Provider shall maintain documentation to demonstrate compliance with PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 until that entity meets all of the requirements of the effective PRC-005-2, or its combined successor standards, in accordance with this implementation plan.

While registered entities are implementing the requirements of PRC-005-2 or its combined successor standards, each registered entity must be prepared to identify:

- All of its applicable Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components, and
- Whether each component has last been maintained according to PRC-005-2 (or its combined successor standards), PRC-005-1b, PRC-008-0, PRC-011-0, PRC-017-0, or a combination thereof.

Effective Date

PRC-005-6 shall become effective on the first day of the first calendar quarter after the date that the standard is approved by an applicable governmental authority or as otherwise provided for in a jurisdiction where approval by an applicable governmental authority is required for a standard to go into effect. Where approval by an applicable governmental authority is not required, the standard shall become effective on the first day of the first calendar quarter after the date the standard is adopted by the NERC Board of Trustees or as otherwise provided for in that jurisdiction.

Retirement of Existing Standards:

Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 shall remain active throughout the phased implementation period of PRC-005-2 and shall be applicable to a registered entity's Protection System Component maintenance activities not yet transitioned to PRC-005-2. Standards PRC-005-1b, PRC-008-0, PRC-011-0, and PRC-017-0 shall be retired at midnight of March 31, 2027 or as otherwise made effective pursuant to the laws applicable to such Electric Reliability Organization (ERO) governmental authorities; or, in those jurisdictions where no regulatory approval is required, at midnight of March 31, 2027.

PRC-005-2 and PRC-005-2(i) shall be retired at midnight of the day immediately prior to the first day of the first calendar quarter, twelve (12) calendar months following applicable regulatory approval of PRC-005-6, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities; or, in those jurisdictions where no regulatory approval is required, the first day of the first calendar quarter from the date of Board of Trustees' adoption.

If approved by FERC prior to the approval of PRC-005-6, PRC-005-2(ii), PRC-005-3, PRC-005-3(i), PRC-005-3(ii), PRC-005-4 and PRC-005-5 shall be retired on the date immediately prior to the first day of the first calendar quarter following regulatory approval of PRC-005-6.

Implementation Plan for Definitions:

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms (Glossary) are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, the Glossary definition will be removed from the individual standard and added to the Glossary. The definitions of terms used only in the standard will remain in the standard.

Glossary Definition:

- None

Definitions of Terms Used in the Standard:

Automatic Reclosing – Includes the following Components:

- Reclosing relay
- Supervisory relay(s) – relay(s) that perform voltage and/or sync check functions that enable or disable operation of the reclosing relay
- Voltage sensing devices associated with the supervisory relay(s)
- Control circuitry associated with the reclosing relay or supervisory relay(s)

Component Type –

- Any one of the five specific elements of a Protection System.

- Any one of the four specific elements of Automatic Reclosing.
- Any one of the two specific elements of Sudden Pressure Relaying.

Component – Any individual discrete piece of equipment included in a Protection System, Automatic Reclosing, or Sudden Pressure Relaying.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-3, and Table 5, which requires corrective action or a Protection System Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component, Automatic Reclosing, or Sudden Pressure Relaying configuration or application errors are not included in Countable Events.

Implementation Plan for New or Revised Definitions:

The revised definitions (Automatic Reclosing, Component, and Countable Event) become effective upon the effective date of PRC-005-6.

Implementation Plan for PRC-005-2 and PRC-005-6

Requirements R1, R2, and R5:

PRC-005-2: For Protection System Components, entities shall be 100% compliant on April 1, 2015 or, in those jurisdictions where no regulatory approval is required, on January 1, 2015 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

PRC-005-6: For Automatic Reclosing Components, Sudden Pressure Relaying Components, and Dispersed Generation Resources, entities shall be 100% compliant on the first day of the first calendar quarter twelve (12) months following applicable regulatory approvals of PRC-005-6 or, in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter twenty-four (24) months following NERC Board of Trustees' adoption of PRC-005-6 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Implementation Plan for Requirements R3 and R4:

PRC-005-2:

1. For Protection System Component maintenance activities with maximum allowable intervals of less than one (1) calendar year, as established in Tables 1-1 through 1-5:
   - The entity shall be 100% compliant on October 1, 2015, or in those jurisdictions where no regulatory approval is required, on July 1, 2016, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

2. For Protection System Component maintenance activities with maximum allowable intervals one (1) calendar year or more, but two (2) calendar years or less, as established in Tables 1-1 through 1-5:

   - The entity shall be 100% compliant on April 1, 2017 or, in those jurisdictions where no regulatory approval is required, on January 1, 2017or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

3. For Protection System Component maintenance activities with maximum allowable intervals of three (3) calendar years, as established in Tables 1-1 through 1-5:

   - The entity shall be at least 30% compliant on April 1, 2016 (or, for generating plants with scheduled outage intervals exceeding two years, at the conclusion of the first succeeding maintenance outage) or, in those jurisdictions where no regulatory approval is required, on January 1, 2016 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant on April 1, 2017 or, in those jurisdictions where no regulatory approval is required, on January 1, 2017 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be 100% compliant on April 1, 2018 or, in those jurisdictions where no regulatory approval is required, on January 1, 2018 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

4. For Protection System Component maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Tables 1-1 through 1-5 and Table 3:

   - The entity shall be at least 30% compliant on April 1, 2017 (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage) or, in those jurisdictions where no regulatory approval is required, on January 1, 2017 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant on April 1, 2019 or, in those jurisdictions where no regulatory approval is required, on January 1, 2019 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be 100% compliant on April 1, 2021 or, in those jurisdictions where no regulatory approval is required, on January 1, 2021 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

5. For Protection System Component maintenance activities with maximum allowable intervals of twelve (12) calendar years, as established in Tables 1-1 through 1-5, Table 2, and Table 3:

- The entity shall be at least 30% compliant on April 1, 2019 or, in those jurisdictions where no regulatory approval is required, on January 1, 2019 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- The entity shall be at least 60% compliant on April 1, 2023 or, in those jurisdictions where no regulatory approval is required, on January 1, 2023 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- The entity shall be 100% compliant on April 1, 2027 or, in those jurisdictions where no regulatory approval is required, on January 1, 2027 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

PRC-005-6:

1. For Automatic Reclosing Components, Sudden Pressure Relaying Components, and Dispersed Generation Resources maintenance activities with maximum allowable intervals of six (6) calendar years, as established in Table 4-1, 4-2(a) and 4-2(b):
   - The entity shall be at least 30% compliant on the first day of the first calendar quarter thirty-six (36) months following applicable regulatory approval of PRC-005-6 (or, for generating plants with scheduled outage intervals exceeding three years, at the conclusion of the first succeeding maintenance outage) or, in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter forty-eight (48) months following NERC Board of Trustees' adoption of PRC-005-6 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be at least 60% compliant on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval of PRC-005-6 or, in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two (72) months following NERC Board of Trustees' adoption of PRC-005-6, or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
   - The entity shall be 100% compliant on the first day of the first calendar quarter eighty-four (84) months following applicable regulatory approval of PRC-005-6 or, in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter ninety-six (96) months following NERC Board of Trustees' adoption of PRC-005-6 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
2. For Automatic Reclosing Components, Sudden Pressure Relaying Components, and Dispersed Generation Resources maintenance activities, with maximum allowable intervals of twelve (12) calendar years, as established in Table 4-1, 4.2(a), or 4.2(b):
   - The entity shall be at least 30% compliant on the first day of the first calendar quarter sixty (60) months following applicable regulatory approval of PRC-005-6 or, in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter seventy-two

(72) months following NERC Board of Trustees' adoption of PRC-005-6 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

- The entity shall be at least 60% compliant on the first day of the first calendar quarter following one hundred eight (108) months following applicable regulatory approval of PRC-005-6 or, in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred twenty (120) months following NERC Board of Trustees' adoption of PRC-005-6 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.
- The entity shall be 100% compliant on the first day of the first calendar quarter one hundred fifty-six (156) months following applicable regulatory approval of PRC-005-6 or, in those jurisdictions where no regulatory approval is required, on the first day of the first calendar quarter one hundred sixty-eight (168) months following NERC Board of Trustees' adoption of PRC-005-6 or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.

Applicability:

This standard applies to the following functional entities:

- Transmission Owner
- Generator Owner
- Distribution Provider

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SAR posted for comment March 12 – April 10, 2015.

Description of Current Draft

This version of PRC-005 is posted for a 45-day concurrent comment and ballot period to address directives from FERC Order No. 803, addressing Automatic Reclosing. Specifically, supervisory relays, associated voltage sensing devices, and associated control circuitry were added.

Anticipated Actions	Anticipated Dates
45-day Formal Comment Period with Parallel Ballot	May 2015 – July 2015
Final ballot	July 2015
BOT adoption	August 2015

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms (Glossary) are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, this defined term will be removed from the individual standard and added to the Glossary.

Automatic Reclosing (see Section 6 of the Standard)

A. Introduction

1. **Title:** **Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance**

2. **Number: PRC-005-6~~5~~**

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems, Automatic Reclosing, and Sudden Pressure Relaying affecting the reliability of the Bulk Electric System (BES) so that they are kept in working order.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owner

   4.1.2 Generator Owner

   4.1.3 Distribution Provider

   4.2. Facilities:

   4.2.1 Protection Systems and Sudden Pressure Relaying that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)

   4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection Systems installed as a Remedial Action Scheme (RAS) for BES reliability.

   4.2.5 Protection Systems and Sudden Pressure Relaying for generator Facilities that are part of the BES, except for generators identified through Inclusion I4 of the BES definition, including:

   4.2.5.1 Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.

   4.2.5.2 Protection Systems and Sudden Pressure Relaying for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection Systems and Sudden Pressure Relaying for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

4.2.6 Protection Systems and Sudden Pressure Relaying for the following BES generator Facilities for dispersed power producing resources identified through Inclusion I4 of the BES definition:

4.2.6.1 Protection Systems and Sudden Pressure Relaying for Facilities used in aggregating dispersed BES generation from the point where those resources aggregate to greater than 75 MVA to a common point of connection at 100kV or above.

4.2.7 Automatic Reclosing[1], including:

4.2.7.1 Automatic Reclosing applied on the terminals of Elements connected to the BES bus located at generating plant substations where the total installed gross generating plant capacity is greater than the gross capacity of the largest BES generating unit within the Balancing Authority Area or, if a member of a Reserve Sharing Group, the largest generating unit within the Reserve Sharing Group.[2]

4.2.7.2 Automatic Reclosing applied on the terminals of all BES Elements at substations one bus away from generating plants specified in Section 4.2.7.1 when the substation is less than 10 circuit-miles from the generating plant substation.

4.2.7.3 Automatic Reclosing applied as an integral part of an RAS specified in Section 4.2.4.

5. **Effective Date:** See the Implementation Plan for this standard.

6. **Definitions Used in this Standard:**

[1] Automatic Reclosing addressed in Section 4.2.7.1 and 4.2.7.2 may be excluded if the equipment owner can demonstrate that a close-in three-phase fault present for twice the normal clearing time (capturing a minimum trip-close-trip time delay) does not result in a total loss of gross generation in the Interconnection exceeding the gross capacity of the largest relevant BES generating unit where the Automatic Reclosing is applied.

[2] The largest BES generating unit within the Balancing Authority Area or the largest generating unit within the Reserve Sharing Group, as applicable, is subject to change. As a result of such a change, the Automatic Reclosing Components subject to the standard could change effective on the date of such change.

Automatic Reclosing – Includes the following Components:

- Reclosing relay
- Supervisory relay(s) – relay(s) that perform voltage and/or sync check functions that enable or disable operation of the reclosing relay
- Voltage sensing devices associated with the supervisory relay(s)
- Control circuitry associated with the reclosing relay or supervisory relay(s)

Rationale for revisions to Automatic Reclosing: To address directives from FERC Order No. 803 addressing Automatic Reclosing, the definition for Automatic Reclosing was revised to add supervisory relays, the associated voltage sensing devices, and the associated control circuitry.

Sudden Pressure Relaying – A system that trips an interrupting device(s) to isolate the equipment it is monitoring and includes the following Components:

- Fault pressure relay – a mechanical relay or device that detects rapid changes in gas pressure, oil pressure, or oil flow that are indicative of Faults within liquid-filled, wire-wound equipment
- Control circuitry associated with a fault pressure relay

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the Component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual Components.

Component Type –

- Any one of the five specific elements of a Protection System.
- Any one of the ~~two~~ four specific elements of Automatic Reclosing.
- Any one of the two specific elements of Sudden Pressure Relaying.

Rationale for revisions to Component Type: With the revision of the definition of Automatic Reclosing, there are four specific elements of this definition, rather than two as stated in the prior version.

Component – Any individual discrete piece of equipment included in a Protection System, Automatic Reclosing, or Sudden Pressure Relaying.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5, Table

3, Tables 4-1 through 4-3~~2~~, and Table 5, which requires corrective action or a Protection System Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component, Automatic Reclosing, or Sudden Pressure Relaying configuration or application errors are not included in Countable Events.

B. Requirements and Measures

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems, Automatic Reclosing, and Sudden Pressure Relaying identified in Section 4.2, Facilities. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning*]

The PSMP shall:

1.1. Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type. All batteries associated with the station ~~dc~~ DC supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

1.2. Include the applicable monitored Component attributes applied to each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3~~2~~, and Table 5 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components.

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a documented PSMP~~rotection System Maintenance Program~~ in accordance with Requirement R1.

For each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type, the documentation shall include the type of maintenance method applied (time-based, performance-based, or a combination of these maintenance methods), and shall include all batteries associated with the station ~~dc~~ DC supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

For Component Types that use monitoring to extend the maintenance intervals, the responsible entity(s) shall have evidence for each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate monitored Component attributes as specified in Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3~~2~~, and Table 5. (Part 1.2)

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2, which may include, but is not limited to, Component lists, dated maintenance records, and dated analysis records and results.

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3~~2~~, and Table 5. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has maintained its Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components included within its time-based program in accordance with Requirement R3. The evidence may include, but is not limited to, dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the PSMP~~rotection System Maintenance Program~~ for the Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components included in its performance-based program in accordance with Requirement R4. The evidence may include, but is not limited to, dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance

Issues in accordance with Requirement R5. The evidence may include, but is not limited to, work orders, replacement Component orders, invoices, project schedules with completed milestones, return material authorizations (RMAs) or purchase orders.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated PSMP~~rotection System Maintenance Program~~, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component Type.

For Requirement R2, Requirement R3, and Requirement R4, in cases where the interval of the maintenance activity is longer than the audit cycle, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performance of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component. In cases where the interval of the maintenance activity is shorter than the audit cycle, documentation of all performances (in accordance with the tables) of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component since the previous scheduled audit date shall be retained.

For Requirement R5 the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of Unresolved Maintenance Issues identified by the entity since the last audit, including all that were resolved since the last audit.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

Table of Compliance Elements

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both (Part 1.1).	The entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both (Part 1.1).	The entity's PSMP failed to specify whether three Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1). OR The entity's PSMP failed to include the applicable monitoring attributes applied to each Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-~~3~~2, and Table 5 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Components (Part 1.2).	The entity failed to establish a PSMP. OR The entity's PSMP failed to specify whether four or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both (Part 1.1). OR The entity's PSMP failed to include applicable station batteries in a time-based program (Part 1.1).
R2	The entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within three years.	NA	The entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within four years.	The entity uses performance-based maintenance intervals in its PSMP but: 1) Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce Countable Events to no more than 4% within five years OR 3) Maintained a Segment with

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR • Annually perform maintenance on the greater of 5% of the Segment population or 3 Components, OR • Annually analyze the program activities and results for each Segment.
R3	For Components included within a time-based maintenance program, the entity failed to maintain 5% or less of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-~~2~~3, and Table 5.	For Components included within a time-based maintenance program, the entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-~~2~~3, and Table 5.	For Components included within a time-based maintenance program, the entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-~~2~~3, and Table 5.	For Components included within a time-based maintenance program, the entity failed to maintain more than 15% of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-~~2~~3, and Table 5.

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R4	For Components included within a performance-based maintenance program, the entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.	For Components included within a performance-based maintenance program, the entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.	For Components included within a performance-based maintenance program, the entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.	For Components included within a performance-based maintenance program, the entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.
R5	The entity failed to undertake efforts to correct 5 or fewer identified Unresolved Maintenance Issues.	The entity failed to undertake efforts to correct greater than 5 but less than or equal to 10 identified Unresolved Maintenance Issues.	The entity failed to undertake efforts to correct greater than 10 but less than or equal to 15 identified Unresolved Maintenance Issues.	The entity failed to undertake efforts to correct greater than 15 identified Unresolved Maintenance Issues.

D. Regional Variances

None.

E. Interpretations

None.

Supplemental Reference Documents

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

2. *Considerations for Maintenance and Testing of Auto-reclosing Schemes*, NERC System Analysis and Modeling Subcommittee, and NERC System Protection and Control Subcommittee (November 2012)
3. *Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities – SPCS Input for Standard Development in Response to FERC Order No. 758,* NERC System Protection and Control Subcommittee (December 2013)
4. *Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities* – Supplemental Information to Support Project 2007-17.3: Protection System Maintenance and Testing (October 31, 2014)

Version History

Version	Date	Action	Change Tracking
0	February 8, 2005	Adopted by NERC Board of Trustees	New.
1	February 7, 2006	Adopted by NERC Board of Trustees	1. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 2. Added “periods” to items where appropriate. Changed “Timeframe” to “Time Frame” in item D, 1.2.
1a	February 17, 2011	Adopted by NERC Board of Trustees	Added Appendix 1 - Interpretation regarding applicability of standard to protection of radially connected transformers developed in Project 2009-17.
1b	November 5,	Adopted by NERC Board of	Interpretation of R1, R1.1, and

Version	Date	Action	Change Tracking
	2009	Trustees	R1.2 developed by Project 2009-10.
1b	February 3, 2012	FERC Order approving revised definition of "Protection System"	Per footnote 8 of FERC's order, the definition of "Protection System" supersedes interpretation "b" of PRC-005-1b upon the effective date of the modified definition (i.e., April 1, 2013). *See N. Amer. Elec. Reliability Corp.*, 138 FERC ¶ 61,095 (February 3, 2012).
1.1b	May 9, 2012	Adopted by NERC Board of Trustees	Errata change developed by Project 2010-07, clarified inclusion of generator interconnection Facility in Generator Owner's responsibility.
2	November 7, 2012	Adopted by NERC Board of Trustees	Project 2007-17 - Complete revision, absorbing maintenance requirements from PRC-005-1.1b, PRC-008-0, PRC-011-0, PRC-017-0.
2	October 17, 2013	Approved by NERC Standards Committee	Errata Change: The Standards Committee approved an errata change to the implementation plan for PRC-005-2 to add the phrase "or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities;" to the second sentence under the "Retirement of Existing Standards" section. (no change to standard version number)
2	March 7, 2014	Adopted by NERC Board of Trustees	Modified R1 VSL in response to FERC directive (no change to standard version number).
2(i)	November 13, 2014	Adopted by NERC Board of Trustees	Applicability section revised by Project 2014-01 to clarify application of Requirements to BES dispersed power producing resources.

Version	Date	Action	Change Tracking
2(ii)	November 13, 2014	Adopted by NERC Board of Trustees	Replaced references to Special Protection System and SPS with Remedial Action Scheme and RAS.
3	November 7, 2013	Adopted by the NERC Board of Trustees	Revised to address the FERC directive in Order No. 758 to include Automatic Reclosing in maintenance programs.
3	February 12, 2014	Approved by NERC Standards Committee	Errata Change: The Standards Committee approved errata changes to correct capitalization of certain defined terms within the definitions of "Unresolved Maintenance Issue" and "Protection System Maintenance Program". The changes will be reflected in the definitions section of PRC-005-3 for "Unresolved Maintenance Issue" and in the NERC Glossary of Terms for "Protection System Maintenance Program". (no change to standard version number)
3	March 7, 2014	Adopted by NERC Board of Trustees	Modified R1 VSL in response to FERC directive (no change to standard version number).
3(i)	November 13, 2014	Adopted by NERC Board of Trustees	Applicability section revised by Project 2014-01 to clarify application of Requirements to BES dispersed power producing resources.
3(ii)	November 13, 2014	Adopted by NERC Board of Trustees	Replaced references to Special Protection System and SPS with Remedial Action Scheme and RAS.
4	November 13, 2014	Adopted by NERC Board of Trustees	Added Sudden Pressure Relaying in response to FERC Order No. 758.
5	TBD		Applicability section revised by Project 2014-01 to clarify application of Requirements to

Version	Date	Action	Change Tracking
			BES dispersed power producing resources.
6	TBD		Revised to add supervisory relays to Automatic Reclosing in accordance with the directives in FERC Order 803.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**[3]	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 Calendar Years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 Calendar Years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[3] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed.
For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**[3]	**Maintenance Activities**
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ~~ac~~ AC measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2).	12 Calendar Years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 Calendar Months	Verify that the communications system is functional.
	6 Calendar Years	Verify that the communications system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communications system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function (See Table 2).	12 Calendar Years	Verify that the communications system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communications system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with all of the following: • Continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 Calendar Years	Verify only the unmonitored communications system inputs and outputs that are essential to proper functioning of the Protection System

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 Calendar Years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements that are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent AC~~ac~~ measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station ~~dc~~ DC Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station ~~dc~~ DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station ~~dc~~ DC supply using Vented Lead-Acid (VLA) batteries not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station ~~dc~~ DC supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack

Table 1-4(a) Component Type – Protection System Station ~~dc~~ DC Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station ~~dc~~ DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station ~~dc~~ DC Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station ~~dc~~ DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station ~~dc~~ DC supply with Valve Regulated Lead-Acid (VRLA) batteries not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station ~~dc~~ DC supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack

Table 1-4(b) Component Type – Protection System Station ~~dc~~ DC Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station ~~dc~~ DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(c) Component Type – Protection System Station ~~dc~~ DC Supply Using Nickel-Cadmium (NiCad) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station ~~dc~~ DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station ~~dc~~ DC supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station ~~dc~~ DC supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack

Table 1-4(c) Component Type – Protection System Station ~~dc~~ DC Supply Using Nickel-Cadmium (NiCad) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station ~~dc~~ DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Years	Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station ~~dc~~ DC Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station ~~dc~~ DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station ~~dc~~ DC supply not using a battery and not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station ~~dc~~ DC supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based ~~dc~~ DC supply
	6 Calendar Years	Verify that the ~~dc~~ DC supply can perform as manufactured when ~~ac~~ ACpower is not present.

Table 1-4(e) Component Type – Protection System Station ~~dc~~ DC Supply for non-BES Interrupting Devices for RAS, non-distributed UFLS, and non-distributed UVLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System ~~dc~~ DC supply used for tripping only non-BES interrupting devices as part of a RAS, non-distributed UFLS, or non-distributed UVLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station ~~dc~~ DC supply voltage.

Table 1-4(f) Exclusions for Protection System Station ~~dc~~ DC Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station ~~dc~~ DC supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure (See Table 2).	No periodic maintenance specified	No periodic verification of station ~~dc~~ DC supply voltage is required.
Any battery based station ~~dc~~ DC supply with electrolyte level monitoring and alarming in every cell (See Table 2).		No periodic inspection of the electrolyte level for each cell is required.
Any station ~~dc~~ DC supply with unintentional ~~dc~~ DC ground monitoring and alarming (See Table 2).		No periodic inspection of unintentional ~~dc~~ DC grounds is required.
Any station ~~dc~~ DC supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station ~~dc~~ DC supply (See Table 2).		No periodic verification of float voltage of battery charger is required.
Any battery based station ~~dc~~ DC supply with monitoring and alarming of battery string continuity (See Table 2).		No periodic verification of the battery continuity is required.
Any battery based station ~~dc~~ DC supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2).		No periodic verification of the intercell and terminal connection resistance is required.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with internal ohmic value or float current monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2).		No periodic evaluation relative to baseline of battery cell/unit measurements indicative of battery performance is required to verify the station battery can perform as manufactured.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ohmic value (See Table 2).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions Excluding distributed UFLS and distributed UVLS (see Table 3), Automatic Reclosing (see Table 4), and Sudden Pressure Relaying (see Table 5) Note: Table requirements apply to all Control Circuitry Components of Protection Systems, and RAS except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with RAS. (See Table 4-2(b) for RAS which include Automatic Reclosing.)	12 Calendar Years	Verify all paths of the control circuits essential for proper operation of the RAS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 Calendar Years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with protective functions and/or RAS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-~~23~~, and Table 5 alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-~~23~~, and Table 5 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 Calendar Years	Verify that settings are as specified. For non-microprocessor relays: • Test and, if necessary calibrate. For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 Calendar Years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent ~~ac~~ AC measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as	12 Calendar Years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
designed, with alarming for failure (See Table 2). Alarming for change of settings (See Table 2).		
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 Calendar Years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System ~~dc~~ DC supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system.	12 Calendar Years	Verify Protection System ~~dc~~ DC supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (excludes non-BES interrupting device trip coils).	12 Calendar Years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems (excludes non-BES interrupting device trip coils).	12 Calendar Years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

Table 4-1 Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Reclosing and Supervisory Relay Note: In cases where Components of Automatic Reclosing are common to Components listed in Table 1-1 through 1-5, the Components only need to be tested once during a distinct maintenance interval.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored reclosing relay or supervisory relay not having all the monitoring attributes of a category below.	6 Calendar Years	Verify that settings are as specified. For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Automatic Reclosing. For microprocessor supervisory relays: • Verify acceptable measurement of power system input values.
Monitored microprocessor reclosing relay or supervisory relay with the following: • Internal self-diagnosis and alarming (See Table 2). • Alarming for power supply failure (See Table 2). For supervisory relay: • Voltage waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics.	12 Calendar Years	Verify: • Settings are as specified. Operation of the relay inputs and outputs that are essential to proper functioning of the Automatic Reclosing. For supervisory relays: • Verify acceptable measurement of power system input values.

Table 4-1 Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Reclosing and Supervisory Relay Note: In cases where Components of Automatic Reclosing are common to Components listed in Table 1-1 through 1-5, the Components only need to be tested once during a distinct maintenance interval.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Monitored microprocessor reclosing relay or supervisory relay with preceding row attributes and the following: • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2). For supervisory relay: • AC measurements are continuously verified by comparison to an independent AC measurement source, with alarming for excessive error (See Table 2).	12 Calendar Years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Automatic Reclosing.

Table 4-2(a) Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Control Circuitry Associated with Reclosing and Supervisory Relays that are NOT an Integral Part of an RAS		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Unmonitored Control circuitry associated with Automatic Reclosing that is not an integral part of an RAS.	12 Calendar Years	Verify that Automatic Reclosing, upon initiation, does not issue a premature closing command to the close circuitry.
Control circuitry associated with Automatic Reclosing that is not part of an RAS and is monitored and alarmed for conditions that would result in a premature closing command. (See Table 2)	No periodic maintenance specified	None.

Table 4-2(b) Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Control Circuitry Associated with Reclosing and Supervisory Relays that ARE an Integral Part of an RAS		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Close coils or actuators of circuit breakers or similar devices that are used in conjunction with Automatic Reclosing as part of an RAS (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify that each close coil or actuator is able to operate the circuit breaker or mitigating device.
Unmonitored close control circuitry associated with Automatic Reclosing used as an integral part of an RAS.	12 Calendar Years	Verify all paths of the control circuits associated with Automatic Reclosing that are essential for proper operation of the RAS.
Control circuitry associated with Automatic Reclosing that is an integral part of an RAS whose integrity is monitored and alarmed. (See Table 2)	No periodic maintenance specified	None.

Table 4-3 Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Voltage Sensing Devices Associated with Supervisory Relays		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage sensing devices not having monitoring attributes of the category below.	12 Calendar Years	Verify that voltage signal values are provided to the supervisory relays.
Voltage sensing devices that are connected to microprocessor supervisory relays with AC measurements that are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent AC measurement source, with alarming for unacceptable error or failure. (See Table 2)	No periodic maintenance specified	None.

Table 5 Maintenance Activities and Intervals for Sudden Pressure Relaying Note: In cases where Components of Sudden Pressure Relaying are common to Components listed in Table 1-5, the Components only need to be tested once during a distinct maintenance interval.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any fault pressure relay.	6 Calendar Years	Verify the pressure or flow sensing mechanism is operable.
Electromechanical lockout devices which are directly in a trip path from the fault pressure relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with Sudden Pressure Relaying.	12 Calendar Years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with Sudden Pressure Relaying whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of Components included in each designated Segment, with a minimum Segment population of 60 Components.
2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-3~~2~~, and Table 5 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.
3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Components and Segments and/or description if any changes occur within the Segment.
2. Perform maintenance on the greater of 5% of the Components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment.
4. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

If the Components in a Segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SAR posted for comment March 12 – April 10, 2015.

Description of Current Draft

This version of PRC-005 is posted for a 45-day concurrent comment and ballot period to address directives from FERC Order No. 803, addressing Automatic Reclosing. Specifically, supervisory relays, associated voltage sensing devices, and associated control circuitry were added.

Anticipated Actions	Anticipated Dates
45-day Formal Comment Period with Parallel Ballot	May 2015 – July 2015
Final ballot	July 2015
BOT adoption	August 2015

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms (Glossary) are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, this defined term will be removed from the individual standard and added to the Glossary.

Automatic Reclosing (see Section 6 of the Standard)

A. Introduction

1. **Title:** **Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance**

2. **Number: PRC-005-6**

3. **Purpose:** To document and implement programs for the maintenance of all Protection Systems, Automatic Reclosing, and Sudden Pressure Relaying affecting the reliability of the Bulk Electric System (BES) so that they are kept in working order.

4. **Applicability:**

   4.1. Functional Entities:

   4.1.1 Transmission Owner

   4.1.2 Generator Owner

   4.1.3 Distribution Provider

   4.2. Facilities:

   4.2.1 Protection Systems and Sudden Pressure Relaying that are installed for the purpose of detecting Faults on BES Elements (lines, buses, transformers, etc.)

   4.2.2 Protection Systems used for underfrequency load-shedding systems installed per ERO underfrequency load-shedding requirements.

   4.2.3 Protection Systems used for undervoltage load-shedding systems installed to prevent system voltage collapse or voltage instability for BES reliability.

   4.2.4 Protection Systems installed as a Remedial Action Scheme (RAS) for BES reliability.

   4.2.5 Protection Systems and Sudden Pressure Relaying for generator Facilities that are part of the BES, except for generators identified through Inclusion I4 of the BES definition, including:

   4.2.5.1 Protection Systems that act to trip the generator either directly or via lockout or auxiliary tripping relays.

   4.2.5.2 Protection Systems and Sudden Pressure Relaying for generator step-up transformers for generators that are part of the BES.

   4.2.5.3 Protection Systems and Sudden Pressure Relaying for station service or excitation transformers connected to the generator bus of generators which are part of the BES, that act to trip the generator either directly or via lockout or tripping auxiliary relays.

4.2.6 Protection Systems and Sudden Pressure Relaying for the following BES generator Facilities for dispersed power producing resources identified through Inclusion I4 of the BES definition:

4.2.6.1 Protection Systems and Sudden Pressure Relaying for Facilities used in aggregating dispersed BES generation from the point where those resources aggregate to greater than 75 MVA to a common point of connection at 100kV or above.

4.2.7 Automatic Reclosing[1], including:

4.2.7.1 Automatic Reclosing applied on the terminals of Elements connected to the BES bus located at generating plant substations where the total installed gross generating plant capacity is greater than the gross capacity of the largest BES generating unit within the Balancing Authority Area or, if a member of a Reserve Sharing Group, the largest generating unit within the Reserve Sharing Group.[2]

4.2.7.2 Automatic Reclosing applied on the terminals of all BES Elements at substations one bus away from generating plants specified in Section 4.2.7.1 when the substation is less than 10 circuit-miles from the generating plant substation.

4.2.7.3 Automatic Reclosing applied as an integral part of an RAS specified in Section 4.2.4.

5. **Effective Date:** See the Implementation Plan for this standard.

6. **Definitions Used in this Standard:**

Automatic Reclosing – Includes the following Components:

- Reclosing relay
- Supervisory relay(s) – relay(s) that perform voltage and/or sync check functions that enable or disable operation of the reclosing relay

Rationale for revisions to Automatic Reclosing: To address directives from FERC Order No. 803 addressing Automatic Reclosing, the definition for Automatic Reclosing was revised to add supervisory relays, the associated voltage sensing devices, and the associated control circuitry.

[1] Automatic Reclosing addressed in Section 4.2.7.1 and 4.2.7.2 may be excluded if the equipment owner can demonstrate that a close-in three-phase fault present for twice the normal clearing time (capturing a minimum trip-close-trip time delay) does not result in a total loss of gross generation in the Interconnection exceeding the gross capacity of the largest relevant BES generating unit where the Automatic Reclosing is applied.

[2] The largest BES generating unit within the Balancing Authority Area or the largest generating unit within the Reserve Sharing Group, as applicable, is subject to change. As a result of such a change, the Automatic Reclosing Components subject to the standard could change effective on the date of such change.

- Voltage sensing devices associated with the supervisory relay(s)
- Control circuitry associated with the reclosing relay or supervisory relay(s)

Sudden Pressure Relaying – A system that trips an interrupting device(s) to isolate the equipment it is monitoring and includes the following Components:

- Fault pressure relay – a mechanical relay or device that detects rapid changes in gas pressure, oil pressure, or oil flow that are indicative of Faults within liquid-filled, wire-wound equipment
- Control circuitry associated with a fault pressure relay

Unresolved Maintenance Issue – A deficiency identified during a maintenance activity that causes the Component to not meet the intended performance, cannot be corrected during the maintenance interval, and requires follow-up corrective action.

Segment – Components of a consistent design standard, or a particular model or type from a single manufacturer that typically share other common elements. Consistent performance is expected across the entire population of a Segment. A Segment must contain at least sixty (60) individual Components.

Component Type –

- Any one of the five specific elements of a Protection System.
- Any one of the four specific elements of Automatic Reclosing.
- Any one of the two specific elements of Sudden Pressure Relaying.

Rationale for revisions to Component Type: With the revision of the definition of Automatic Reclosing, there are four specific elements of this definition, rather than two as stated in the prior version.

Component – Any individual discrete piece of equipment included in a Protection System, Automatic Reclosing, or Sudden Pressure Relaying.

Countable Event – A failure of a Component requiring repair or replacement, any condition discovered during the maintenance activities in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-3, and Table 5, which requires corrective action or a Protection System Misoperation attributed to hardware failure or calibration failure. Misoperations due to product design errors, software errors, relay settings different from specified settings, Protection System Component, Automatic Reclosing, or Sudden Pressure Relaying configuration or application errors are not included in Countable Events.

B. Requirements and Measures

R1. Each Transmission Owner, Generator Owner, and Distribution Provider shall establish a Protection System Maintenance Program (PSMP) for its Protection Systems, Automatic Reclosing, and Sudden Pressure Relaying identified in Section 4.2, Facilities. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning*]

The PSMP shall:

1.1. Identify which maintenance method (time-based, performance-based per PRC-005 Attachment A, or a combination) is used to address each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type. All batteries associated with the station DC supply Component Type of a Protection System shall be included in a time-based program as described in Table 1-4 and Table 3.

1.2. Include the applicable monitored Component attributes applied to each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3, and Table 5 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components.

M1. Each Transmission Owner, Generator Owner and Distribution Provider shall have a documented PSMP in accordance with Requirement R1.

For each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type, the documentation shall include the type of maintenance method applied (time-based, performance-based, or a combination of these maintenance methods), and shall include all batteries associated with the station DC supply Component Types in a time-based program as described in Table 1-4 and Table 3. (Part 1.1)

For Component Types that use monitoring to extend the maintenance intervals, the responsible entity(s) shall have evidence for each Protection System, Automatic Reclosing, and Sudden Pressure Relaying Component Type (such as manufacturer's specifications or engineering drawings) of the appropriate monitored Component attributes as specified in Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3, and Table 5. (Part 1.2)

R2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals in its PSMP shall follow the procedure established in PRC-005 Attachment A to establish and maintain its performance-based intervals. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M2. Each Transmission Owner, Generator Owner, and Distribution Provider that uses performance-based maintenance intervals shall have evidence that its current performance-based maintenance program(s) is in accordance with Requirement R2,

which may include, but is not limited to, Component lists, dated maintenance records, and dated analysis records and results.

R3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall maintain its Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components that are included within the time-based maintenance program in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Table 4-1 through 4-3, and Table 5. *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M3. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes time-based maintenance program(s) shall have evidence that it has maintained its Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components included within its time-based program in accordance with Requirement R3. The evidence may include, but is not limited to, dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

R4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance program(s) in accordance with Requirement R2 shall implement and follow its PSMP for its Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components that are included within the performance-based program(s). *[Violation Risk Factor: High] [Time Horizon: Operations Planning]*

M4. Each Transmission Owner, Generator Owner, and Distribution Provider that utilizes performance-based maintenance intervals in accordance with Requirement R2 shall have evidence that it has implemented the PSMP for the Protection System, Automatic Reclosing, and Sudden Pressure Relaying Components included in its performance-based program in accordance with Requirement R4. The evidence may include, but is not limited to, dated maintenance records, dated maintenance summaries, dated check-off lists, dated inspection records, or dated work orders.

R5. Each Transmission Owner, Generator Owner, and Distribution Provider shall demonstrate efforts to correct identified Unresolved Maintenance Issues. *[Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M5. Each Transmission Owner, Generator Owner, and Distribution Provider shall have evidence that it has undertaken efforts to correct identified Unresolved Maintenance Issues in accordance with Requirement R5. The evidence may include, but is not limited to, work orders, replacement Component orders, invoices, project schedules with completed milestones, return material authorizations (RMAs) or purchase orders.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority

As defined in the NERC Rules of Procedure, "Compliance Enforcement Authority" means NERC or the Regional Entity in their respective roles of monitoring and enforcing compliance with the NERC Reliability Standards.

1.2. Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner, Generator Owner, and Distribution Provider shall each keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

For Requirement R1, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep its current dated PSMP, as well as any superseded versions since the preceding compliance audit, including the documentation that specifies the type of maintenance program applied for each Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component Type.

For Requirement R2, Requirement R3, and Requirement R4, in cases where the interval of the maintenance activity is longer than the audit cycle, the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of the most recent performance of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component. In cases where the interval of the maintenance activity is shorter than the audit cycle, documentation of all performances (in accordance with the tables) of that maintenance activity for the Protection System, Automatic Reclosing, or Sudden Pressure Relaying Component since the previous scheduled audit date shall be retained.

For Requirement R5 the Transmission Owner, Generator Owner, and Distribution Provider shall each keep documentation of Unresolved Maintenance Issues identified by the entity since the last audit, including all that were resolved since the last audit.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3. Compliance Monitoring and Assessment Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

1.4. Additional Compliance Information

None

Table of Compliance Elements

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1	The entity's PSMP failed to specify whether one Component Type is being addressed by time-based or performance-based maintenance, or a combination of both (Part 1.1).	The entity's PSMP failed to specify whether two Component Types are being addressed by time-based or performance-based maintenance, or a combination of both (Part 1.1).	The entity's PSMP failed to specify whether three Component Types are being addressed by time-based or performance-based maintenance, or a combination of both. (Part 1.1). OR The entity's PSMP failed to include the applicable monitoring attributes applied to each Component Type consistent with the maintenance intervals specified in Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-3, and Table 5 where monitoring is used to extend the maintenance intervals beyond those specified for unmonitored Components (Part 1.2).	The entity failed to establish a PSMP. OR The entity's PSMP failed to specify whether four or more Component Types are being addressed by time-based or performance-based maintenance, or a combination of both (Part 1.1). OR The entity's PSMP failed to include applicable station batteries in a time-based program (Part 1.1).
R2	The entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within three years.	NA	The entity uses performance-based maintenance intervals in its PSMP but failed to reduce Countable Events to no more than 4% within four years.	The entity uses performance-based maintenance intervals in its PSMP but: 1) Failed to establish the technical justification described within Requirement R2 for the initial use of the performance-based PSMP OR 2) Failed to reduce Countable Events to no more than 4% within five years OR

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
				3) Maintained a Segment with less than 60 Components OR 4) Failed to: • Annually update the list of Components, OR • Annually perform maintenance on the greater of 5% of the Segment population or 3 Components, OR • Annually analyze the program activities and results for each Segment.
R3	For Components included within a time-based maintenance program, the entity failed to maintain 5% or less of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-3, and Table 5.	For Components included within a time-based maintenance program, the entity failed to maintain more than 5% but 10% or less of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-3, and Table 5.	For Components included within a time-based maintenance program, the entity failed to maintain more than 10% but 15% or less of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-3, and Table 5.	For Components included within a time-based maintenance program, the entity failed to maintain more than 15% of the total Components included within a specific Component Type in accordance with the minimum maintenance activities and maximum maintenance intervals prescribed within Tables 1-1 through 1-5, Table 2, Table 3, Tables 4-1 through 4-3, and Table 5.

Requirement Number	Lower VSL	Moderate VSL	High VSL	Severe VSL
R4	For Components included within a performance-based maintenance program, the entity failed to maintain 5% or less of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.	For Components included within a performance-based maintenance program, the entity failed to maintain more than 5% but 10% or less of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.	For Components included within a performance-based maintenance program, the entity failed to maintain more than 10% but 15% or less of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.	For Components included within a performance-based maintenance program, the entity failed to maintain more than 15% of the annual scheduled maintenance for a specific Component Type in accordance with their performance-based PSMP.
R5	The entity failed to undertake efforts to correct 5 or fewer identified Unresolved Maintenance Issues.	The entity failed to undertake efforts to correct greater than 5 but less than or equal to 10 identified Unresolved Maintenance Issues.	The entity failed to undertake efforts to correct greater than 10 but less than or equal to 15 identified Unresolved Maintenance Issues.	The entity failed to undertake efforts to correct greater than 15 identified Unresolved Maintenance Issues.

D. Regional Variances

None.

E. Interpretations

None.

Supplemental Reference Documents

The following documents present a detailed discussion about determination of maintenance intervals and other useful information regarding establishment of a maintenance program.

1. *Supplementary Reference and FAQ - PRC-005 Protection System Maintenance,* Protection System Maintenance and Testing Standard Drafting Team (April 2015)
2. *Considerations for Maintenance and Testing of Auto-reclosing Schemes*, NERC System Analysis and Modeling Subcommittee, and NERC System Protection and Control Subcommittee (November 2012)
3. *Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities – SPCS Input for Standard Development in Response to FERC Order No. 758,* NERC System Protection and Control Subcommittee (December 2013)
4. *Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities* – Supplemental Information to Support Project 2007-17.3: Protection System Maintenance and Testing (October 31, 2014)

Version History

Version	Date	Action	Change Tracking
0	February 8, 2005	Adopted by NERC Board of Trustees	New.
1	February 7, 2006	Adopted by NERC Board of Trustees	1. Changed incorrect use of certain hyphens (-) to “en dash” (–) and “em dash (—).” 2. Added “periods” to items where appropriate. Changed “Timeframe” to “Time Frame” in item D, 1.2.
1a	February 17, 2011	Adopted by NERC Board of Trustees	Added Appendix 1 - Interpretation regarding applicability of standard to protection of radially connected transformers developed in Project 2009-17.

Version	Date	Action	Change Tracking
1b	November 5, 2009	Adopted by NERC Board of Trustees	Interpretation of R1, R1.1, and R1.2 developed by Project 2009-10.
1b	February 3, 2012	FERC Order approving revised definition of "Protection System"	Per footnote 8 of FERC's order, the definition of "Protection System" supersedes interpretation "b" of PRC-005-1b upon the effective date of the modified definition (i.e., April 1, 2013). *See N. Amer. Elec. Reliability Corp.*, 138 FERC ¶ 61,095 (February 3, 2012).
1.1b	May 9, 2012	Adopted by NERC Board of Trustees	Errata change developed by Project 2010-07, clarified inclusion of generator interconnection Facility in Generator Owner's responsibility.
2	November 7, 2012	Adopted by NERC Board of Trustees	Project 2007-17 - Complete revision, absorbing maintenance requirements from PRC-005-1.1b, PRC-008-0, PRC-011-0, PRC-017-0.
2	October 17, 2013	Approved by NERC Standards Committee	Errata Change: The Standards Committee approved an errata change to the implementation plan for PRC-005-2 to add the phrase "or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities;" to the second sentence under the "Retirement of Existing Standards" section. (no change to standard version number)
2	March 7, 2014	Adopted by NERC Board of Trustees	Modified R1 VSL in response to FERC directive (no change to standard version number).
2(i)	November 13, 2014	Adopted by NERC Board of Trustees	Applicability section revised by Project 2014-01 to clarify application of Requirements to BES dispersed power producing resources.

Version	Date	Action	Change Tracking
2(ii)	November 13, 2014	Adopted by NERC Board of Trustees	Replaced references to Special Protection System and SPS with Remedial Action Scheme and RAS.
3	November 7, 2013	Adopted by the NERC Board of Trustees	Revised to address the FERC directive in Order No. 758 to include Automatic Reclosing in maintenance programs.
3	February 12, 2014	Approved by NERC Standards Committee	Errata Change: The Standards Committee approved errata changes to correct capitalization of certain defined terms within the definitions of “Unresolved Maintenance Issue” and “Protection System Maintenance Program”. The changes will be reflected in the definitions section of PRC-005-3 for “Unresolved Maintenance Issue” and in the NERC Glossary of Terms for “Protection System Maintenance Program". (no change to standard version number)
3	March 7, 2014	Adopted by NERC Board of Trustees	Modified R1 VSL in response to FERC directive (no change to standard version number).
3(i)	November 13, 2014	Adopted by NERC Board of Trustees	Applicability section revised by Project 2014-01 to clarify application of Requirements to BES dispersed power producing resources.
3(ii)	November 13, 2014	Adopted by NERC Board of Trustees	Replaced references to Special Protection System and SPS with Remedial Action Scheme and RAS.
4	November 13, 2014	Adopted by NERC Board of Trustees	Added Sudden Pressure Relaying in response to FERC Order No. 758.

Version	Date	Action	Change Tracking
5	TBD		Applicability section revised by Project 2014-01 to clarify application of Requirements to BES dispersed power producing resources.
6	TBD		Revised to add supervisory relays to Automatic Reclosing in accordance with the directives in FERC Order 803.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**[3]	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 Calendar Years	For all unmonitored relays: • Verify that settings are as specified For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (see Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. • Alarming for power supply failure (see Table 2).	12 Calendar Years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.

[3] For the tables in this standard, a calendar year starts on the first day of a new year (January 1) after a maintenance activity has been completed. For the tables in this standard, a calendar month starts on the first day of the first month after a maintenance activity has been completed.

Table 1-1 Component Type - Protective Relay Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**[3]	**Maintenance Activities**
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent AC measurement source, with alarming for excessive error (See Table 2). • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2).	12 Calendar Years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 1-2 Component Type - Communications Systems Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored communications system necessary for correct operation of protective functions, and not having all the monitoring attributes of a category below.	4 Calendar Months	Verify that the communications system is functional.
	6 Calendar Years	Verify that the communications system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communications system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function (See Table 2).	12 Calendar Years	Verify that the communications system meets performance criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate). Verify operation of communications system inputs and outputs that are essential to proper functioning of the Protection System.
Any communications system with all of the following: • Continuous monitoring or periodic automated testing for the performance of the channel using criteria pertinent to the communications technology applied (e.g. signal level, reflected power, or data error rate, and alarming for excessive performance degradation). (See Table 2) • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2).	12 Calendar Years	Verify only the unmonitored communications system inputs and outputs that are essential to proper functioning of the Protection System

Table 1-3 Component Type - Voltage and Current Sensing Devices Providing Inputs to Protective Relays Excluding distributed UFLS and distributed UVLS (see Table 3)		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage and current sensing devices not having monitoring attributes of the category below.	12 Calendar Years	Verify that current and voltage signal values are provided to the protective relays.
Voltage and Current Sensing devices connected to microprocessor relays with AC measurements that are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent AC measurement source, with alarming for unacceptable error or failure (see Table 2).	No periodic maintenance specified	None.

Table 1-4(a) Component Type – Protection System Station DC Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station DC supply using Vented Lead-Acid (VLA) batteries not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station DC supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells where cells are visible – or measure battery cell/unit internal ohmic values where the cells are not visible • Physical condition of battery rack

Table 1-4(a) Component Type – Protection System Station DC Supply Using Vented Lead-Acid (VLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	18 Calendar Months -or- 6 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(b) Component Type – Protection System Station DC Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station DC supply with Valve Regulated Lead-Acid (VRLA) batteries not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station DC supply voltage Inspect: • For unintentional grounds
	6 Calendar Months	Inspect: • Condition of all individual units by measuring battery cell/unit internal ohmic values.
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Physical condition of battery rack

Table 1-4(b) Component Type – Protection System Station DC Supply Using Valve-Regulated Lead-Acid (VRLA) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS systems, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Months -or- 3 Calendar Years	Verify that the station battery can perform as manufactured by evaluating cell/unit measurements indicative of battery performance (e.g. internal ohmic values or float current) against the station battery baseline. -or- Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(c) Component Type – Protection System Station DC Supply Using Nickel-Cadmium (NiCad) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Protection System Station DC supply **Nickel-Cadmium (NiCad) batteries** not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station DC supply voltage Inspect: • Electrolyte level • For unintentional grounds
	18 Calendar Months	Verify: • Float voltage of battery charger • Battery continuity • Battery terminal connection resistance • Battery intercell or unit-to-unit connection resistance Inspect: • Cell condition of all individual battery cells. • Physical condition of battery rack

Table 1-4(c) Component Type – Protection System Station DC Supply Using Nickel-Cadmium (NiCad) Batteries Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
	6 Calendar Years	Verify that the station battery can perform as manufactured by conducting a performance or modified performance capacity test of the entire battery bank.

Table 1-4(d) Component Type – Protection System Station DC Supply Using Non Battery Based Energy Storage Excluding distributed UFLS and distributed UVLS (see Table 3) Protection System Station DC supply used only for non-BES interrupting devices for RAS, non-distributed UFLS system, or non-distributed UVLS systems is excluded (see Table 1-4(e)).		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System station DC supply not using a battery and not having monitoring attributes of Table 1-4(f).	4 Calendar Months	Verify: • Station DC supply voltage Inspect: • For unintentional grounds
	18 Calendar Months	Inspect: Condition of non-battery based DC supply
	6 Calendar Years	Verify that the DC supply can perform as manufactured when ACpower is not present.

Table 1-4(e) Component Type – Protection System Station DC Supply for non-BES Interrupting Devices for RAS, non-distributed UFLS, and non-distributed UVLS systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any Protection System DC supply used for tripping only non-BES interrupting devices as part of a RAS, non-distributed UFLS, or non-distributed UVLS system and not having monitoring attributes of Table 1-4(f).	When control circuits are verified (See Table 1-5)	Verify Station DC supply voltage.

Table 1-4(f) Exclusions for Protection System Station DC Supply Monitoring Devices and Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any station DC supply with high and low voltage monitoring and alarming of the battery charger voltage to detect charger overvoltage and charger failure (See Table 2).	No periodic maintenance specified	No periodic verification of station DC supply voltage is required.
Any battery based station DC supply with electrolyte level monitoring and alarming in every cell (See Table 2).		No periodic inspection of the electrolyte level for each cell is required.
Any station DC supply with unintentional DC ground monitoring and alarming (See Table 2).		No periodic inspection of unintentional DC grounds is required.
Any station DC supply with charger float voltage monitoring and alarming to ensure correct float voltage is being applied on the station DC supply (See Table 2).		No periodic verification of float voltage of battery charger is required.
Any battery based station DC supply with monitoring and alarming of battery string continuity (See Table 2).		No periodic verification of the battery continuity is required.
Any battery based station DC supply with monitoring and alarming of the intercell and/or terminal connection detail resistance of the entire battery (See Table 2).		No periodic verification of the intercell and terminal connection resistance is required.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with internal ohmic value or float current monitoring and alarming, and evaluating present values relative to baseline internal ohmic values for every cell/unit (See Table 2).		No periodic evaluation relative to baseline of battery cell/unit measurements indicative of battery performance is required to verify the station battery can perform as manufactured.
Any Valve Regulated Lead-Acid (VRLA) or Vented Lead-Acid (VLA) station battery with monitoring and alarming of each cell/unit internal ohmic value (See Table 2).		No periodic inspection of the condition of all individual units by measuring battery cell/unit internal ohmic values of a station VRLA or Vented Lead-Acid (VLA) battery is required.

Table 1-5 Component Type - Control Circuitry Associated With Protective Functions Excluding distributed UFLS and distributed UVLS (see Table 3), Automatic Reclosing (see Table 4), and Sudden Pressure Relaying (see Table 5) Note: Table requirements apply to all Control Circuitry Components of Protection Systems, and RAS except as noted.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Trip coils or actuators of circuit breakers, interrupting devices, or mitigating devices (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify that each trip coil is able to operate the circuit breaker, interrupting device, or mitigating device.
Electromechanical lockout devices which are directly in a trip path from the protective relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with RAS. (See Table 4-2(b) for RAS which include Automatic Reclosing.)	12 Calendar Years	Verify all paths of the control circuits essential for proper operation of the RAS.
Unmonitored control circuitry associated with protective functions inclusive of all auxiliary relays.	12 Calendar Years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with protective functions and/or RAS whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

Table 2 – Alarming Paths and Monitoring In Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-3, and Table 5 alarm attributes used to justify extended maximum maintenance intervals and/or reduced maintenance activities are subject to the following maintenance requirements		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any alarm path through which alarms in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-3, and Table 5 are conveyed from the alarm origin to the location where corrective action can be initiated, and not having all the attributes of the "Alarm Path with monitoring" category below. Alarms are reported within 24 hours of detection to a location where corrective action can be initiated.	12 Calendar Years	Verify that the alarm path conveys alarm signals to a location where corrective action can be initiated.
Alarm Path with monitoring: The location where corrective action is taken receives an alarm within 24 hours for failure of any portion of the alarming path from the alarm origin to the location where corrective action can be initiated.	No periodic maintenance specified	None.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored protective relay not having all the monitoring attributes of a category below.	6 Calendar Years	Verify that settings are as specified. For non-microprocessor relays: • Test and, if necessary calibrate. For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Verify acceptable measurement of power system input values.
Monitored microprocessor protective relay with the following: • Internal self-diagnosis and alarming (See Table 2). • Voltage and/or current waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics. Alarming for power supply failure (See Table 2).	12 Calendar Years	Verify: • Settings are as specified. • Operation of the relay inputs and outputs that are essential to proper functioning of the Protection System. • Acceptable measurement of power system input values.
Monitored microprocessor protective relay with preceding row attributes and the following: • Ac measurements are continuously verified by comparison to an independent AC measurement source, with alarming for excessive error (See Table 2).	12 Calendar Years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Protection System.

Table 3 Maintenance Activities and Intervals for distributed UFLS and distributed UVLS Systems		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
• Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). Alarming for change of settings (See Table 2).		
Voltage and/or current sensing devices associated with UFLS or UVLS systems.	12 Calendar Years	Verify that current and/or voltage signal values are provided to the protective relays.
Protection System DC supply for tripping non-BES interrupting devices used only for a UFLS or UVLS system.	12 Calendar Years	Verify Protection System DC supply voltage.
Control circuitry between the UFLS or UVLS relays and electromechanical lockout and/or tripping auxiliary devices (excludes non-BES interrupting device trip coils).	12 Calendar Years	Verify the path from the relay to the lockout and/or tripping auxiliary relay (including essential supervisory logic).
Electromechanical lockout and/or tripping auxiliary devices associated only with UFLS or UVLS systems (excludes non-BES interrupting device trip coils).	12 Calendar Years	Verify electrical operation of electromechanical lockout and/or tripping auxiliary devices.
Control circuitry between the electromechanical lockout and/or tripping auxiliary devices and the non-BES interrupting devices in UFLS or UVLS systems, or between UFLS or UVLS relays (with no interposing electromechanical lockout or auxiliary device) and the non-BES interrupting devices (excludes non-BES interrupting device trip coils).	No periodic maintenance specified	None.
Trip coils of non-BES interrupting devices in UFLS or UVLS systems.	No periodic maintenance specified	None.

Table 4-1 Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Reclosing and Supervisory Relay Note: In cases where Components of Automatic Reclosing are common to Components listed in Table 1-1 through 1-5, the Components only need to be tested once during a distinct maintenance interval.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any unmonitored reclosing relay or supervisory relay not having all the monitoring attributes of a category below.	6 Calendar Years	Verify that settings are as specified. For non-microprocessor relays: • Test and, if necessary calibrate For microprocessor relays: • Verify operation of the relay inputs and outputs that are essential to proper functioning of the Automatic Reclosing. For microprocessor supervisory relays: • Verify acceptable measurement of power system input values.
• Monitored microprocessor reclosing relay or supervisory relay with the following: Internal self-diagnosis and alarming (See Table 2). • Alarming for power supply failure (See Table 2). For supervisory relay: • Voltage waveform sampling three or more times per power cycle, and conversion of samples to numeric values for measurement calculations by microprocessor electronics.	12 Calendar Years	Verify: • Settings are as specified. Operation of the relay inputs and outputs that are essential to proper functioning of the Automatic Reclosing. For supervisory relays: • Verify acceptable measurement of power system input values.

Table 4-1 Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Reclosing and Supervisory Relay Note: In cases where Components of Automatic Reclosing are common to Components listed in Table 1-1 through 1-5, the Components only need to be tested once during a distinct maintenance interval.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Monitored microprocessor reclosing relay or supervisory relay with preceding row attributes and the following: • Some or all binary or status inputs and control outputs are monitored by a process that continuously demonstrates ability to perform as designed, with alarming for failure (See Table 2). • Alarming for change of settings (See Table 2). For supervisory relay: • AC measurements are continuously verified by comparison to an independent AC measurement source, with alarming for excessive error (See Table 2).	12 Calendar Years	Verify only the unmonitored relay inputs and outputs that are essential to proper functioning of the Automatic Reclosing.

Table 4-2(a) Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Control Circuitry Associated with Reclosing and Supervisory Relays that are NOT an Integral Part of an RAS		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Unmonitored Control circuitry associated with Automatic Reclosing that is not an integral part of an RAS.	12 Calendar Years	Verify that Automatic Reclosing, upon initiation, does not issue a premature closing command to the close circuitry.
Control circuitry associated with Automatic Reclosing that is not part of an RAS and is monitored and alarmed for conditions that would result in a premature closing command. (See Table 2)	No periodic maintenance specified	None.

Table 4-2(b) Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Control Circuitry Associated with Reclosing and Supervisory Relays that ARE an Integral Part of an RAS		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Close coils or actuators of circuit breakers or similar devices that are used in conjunction with Automatic Reclosing as part of an RAS (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify that each close coil or actuator is able to operate the circuit breaker or mitigating device.
Unmonitored close control circuitry associated with Automatic Reclosing used as an integral part of an RAS.	12 Calendar Years	Verify all paths of the control circuits associated with Automatic Reclosing that are essential for proper operation of the RAS.
Control circuitry associated with Automatic Reclosing that is an integral part of an RAS whose integrity is monitored and alarmed. (See Table 2)	No periodic maintenance specified	None.

Table 4-3 Maintenance Activities and Intervals for Automatic Reclosing Components Component Type – Voltage Sensing Devices Associated with Supervisory Relays		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any voltage sensing devices not having monitoring attributes of the category below.	12 Calendar Years	Verify that voltage signal values are provided to the supervisory relays.
Voltage sensing devices that are connected to microprocessor supervisory relays with AC measurements that are continuously verified by comparison of sensing input value, as measured by the microprocessor relay, to an independent AC measurement source, with alarming for unacceptable error or failure. (See Table 2)	No periodic maintenance specified	None.

Table 5 Maintenance Activities and Intervals for Sudden Pressure Relaying Note: In cases where Components of Sudden Pressure Relaying are common to Components listed in Table 1-5, the Components only need to be tested once during a distinct maintenance interval.		
Component Attributes	**Maximum Maintenance Interval**	**Maintenance Activities**
Any fault pressure relay.	6 Calendar Years	Verify the pressure or flow sensing mechanism is operable.
Electromechanical lockout devices which are directly in a trip path from the fault pressure relay to the interrupting device trip coil (regardless of any monitoring of the control circuitry).	6 Calendar Years	Verify electrical operation of electromechanical lockout devices.
Unmonitored control circuitry associated with Sudden Pressure Relaying.	12 Calendar Years	Verify all paths of the trip circuits inclusive of all auxiliary relays through the trip coil(s) of the circuit breakers or other interrupting devices.
Control circuitry associated with Sudden Pressure Relaying whose integrity is monitored and alarmed (See Table 2).	No periodic maintenance specified	None.

PRC-005 — Attachment A

Criteria for a Performance-Based Protection System Maintenance Program

Purpose: To establish a technical basis for initial and continued use of a performance-based Protection System Maintenance Program (PSMP).

To establish the technical justification for the initial use of a performance-based PSMP:

1. Develop a list with a description of Components included in each designated Segment, with a minimum Segment population of 60 Components.
2. Maintain the Components in each Segment according to the time-based maximum allowable intervals established in Tables 1-1 through 1-5, Table 3, Tables 4-1 through 4-3, and Table 5 until results of maintenance activities for the Segment are available for a minimum of 30 individual Components of the Segment.
3. Document the maintenance program activities and results for each Segment, including maintenance dates and Countable Events for each included Component.
4. Analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment and develop maintenance intervals.
5. Determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

To maintain the technical justification for the ongoing use of a performance-based PSMP:

1. At least annually, update the list of Components and Segments and/or description if any changes occur within the Segment.
2. Perform maintenance on the greater of 5% of the Components (addressed in the performance based PSMP) in each Segment or 3 individual Components within the Segment in each year.
3. For the prior year, analyze the maintenance program activities and results for each Segment to determine the overall performance of the Segment.
4. Using the prior year's data, determine the maximum allowable maintenance interval for each Segment such that the Segment experiences Countable Events on no more than 4% of the Components within the Segment, for the greater of either the last 30 Components maintained or all Components maintained in the previous year.

If the Components in a Segment maintained through a performance-based PSMP experience 4% or more Countable Events, develop, document, and implement an action plan to reduce the Countable Events to less than 4% of the Segment population within 3 years.

Rationale:

During development of this standard, text boxes were embedded within the standard to explain the rationale for various parts of the standard. Upon BOT approval, the text from the rationale text boxes was moved to this section.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Standards Authorization Request Form

When completed, email this form to:
Valerie.Agnew@nerc.net

For questions about this form or for assistance in completing the form, call Valerie Agnew at 404-446-2566.

NERC welcomes suggestions for improving the reliability of the Bulk-Power System through improved Reliability Standards. Please use this form to submit your proposal for a new NERC Reliability Standard or a revision to an existing standard.

Request to propose a new or a revision to a Reliability Standard			
Proposed Standard:	PRC-005-6		
Date Submitted:	May 21, 2015		
SAR Requester Information			
Name:	Charles Rogers		
Organization:	Protection System Maintenance Standard Drafting Team		
Telephone:	517-788-0027	E-mail:	Charles.Rogers@cmsenergy.com
SAR Type (Check as many as applicable)			
☐ New Standard		☐ Withdrawal of existing Standard	
☒ Revision to existing Standard		☐ Urgent Action	

SAR Information
Industry Need (What is the industry problem this request is trying to solve?):
In Order No. 803, FERC approved Standard PRC-005-3 and, in Paragraph 31, directed that: "...pursuant to section 215(d)(5) of the FPA, NERC develop modifications to PRC-005-3 to include supervisory devices associated with auto-reclosing relay schemes to which the Reliability Standard applies. Further, we clarify that NERC's proposal regarding the scope of supervisory devices is an acceptable approach to satisfy the Commission directive. Specifically, NERC proposed in its NOPR comments, and we find acceptable, that the scope of the supervisory devices to be encompassed in the Reliability Standard are those providing voltage supervision, supervisory inputs associated with selective auto-reclosing, and sync-check relays that are part of a reclosing scheme covered by PRC-005-3."

SAR Information
Purpose or Goal (How does this request propose to address the problem described above?):
The SDT shall consider modifications, as needed, to address the FERC directive contained in Order 803 resulting from the Commission's consideration of PRC-005-3. The Supplementary Reference Document (provided as a technical reference for PRC-005-3) should also be modified to provide the rationale for the maintenance activities and intervals within the revised standard, as well as to provide application guidance to industry.
Identify the Objectives of the proposed standard's requirements (What specific reliability deliverables are required to achieve the goal?):
Provide clear, unambiguous requirements, standard specific definitions standard(s), and advisory guidance to address the directives in FERC Order 803.
Brief Description (Provide a paragraph that describes the scope of this standard action.)
The Standard Drafting Team (SDT) shall modify NERC Standard PRC-005-3 to explicitly address the directive in Order 803. The SDT shall also consider changes to the standard and supporting documents that provide consistency and alignment with other Reliability Standards.

SAR Information
Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR. Also provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)
The SDTs execution of this SAR requires the SDT to address the directive in FERC Order 803. The SDT will develop requirement(s) to include supervisory devices associated with automatic reclosing relay schemes to which the Reliability Standard applies. The SDT may elect to propose revisions to the standard regarding the scope of supervisory devices as an acceptable approach to satisfy the Commission directive, as proposed in the NOPR comments submitted by NERC. Specifically, NERC proposed that the scope of the supervisory devices to be encompassed in the Reliability Standard are those providing voltage supervision, supervisory inputs associated with selective automatic reclosing, and synchronism check relays that are part of a reclosing scheme covered by PRC-005-3. The SDT shall also: 1. Revise the Implementation Plans for PRC-002i, PRC-005-2ii, PRC-005-3, PRC-005-3i, PRC-005-3ii, PRC-005-4 and PRC-005-5 as needed to facilitate consistent and systematic implementation. 2. Modify the informative Supplementary Reference Document (provided as a technical reference for PRC-005-3) as necessary to provide application guidance to industry.

Reliability Functions	
The Standard will Apply to the Following Functions (Check each one that applies.)	
☐ Regional Reliability Organization	Conducts the regional activities related to planning and operations, and coordinates activities of Responsible Entities to secure the reliability of the Bulk Electric System within the region and adjacent regions.
☐ Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.

Reliability Functions	
☒ Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐ Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐ Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐ Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐ Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐ Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒ Transmission Owner	Owns and maintains transmission facilities.
☐ Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☒ Distribution Provider	Delivers electrical energy to the End-use customer.
☒ Generator Owner	Owns and maintains generation facilities.
☐ Generator Operator	Operates generation unit(s) to provide real and reactive power.
The Standard will Apply to the Following Functions (Check each one that applies.)	
☐ Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐ Market Operator	Interface point for reliability functions with commercial functions.
☐ Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles		
Applicable Reliability Principles (Check all that apply).		
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.	
☐	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.	
☐	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.	
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.	
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.	
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.	
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.	
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.	
Does the proposed Standard comply with all of the following Market Interface Principles?		Enter (yes/no)
	1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
	2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
Does the proposed Standard comply with all of the following Market Interface Principles?		Enter (yes/no)
	3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
	4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

APPENDIX A: LIST OF STANDARDS 39

APPENDIX B: LIST OF STANDARDS RECOMMENDED FOR FURTHER REVIEW 40

1 Executive Summary

The purpose of this White Paper is to provide background and technical rationale for proposed revisions to the applicability of several North American Electric Reliability Corporation (NERC) Reliability Standards, and in some cases the standard requirements. The goal of the NERC Project 2014-01 Standards Applicability for Dispersed Generation Resources[1] standard drafting team (SDT) is to ensure that the Generator Owners (GOs) and Generator Operators (GOPs) of dispersed power producing resources are appropriately assigned responsibility for requirements that impact the reliability of the Bulk Power System (BPS), as the characteristics of operating dispersed power producing resources can be unique. In light of the revised Bulk Electric System (BES) definition approved by the Federal Energy Regulatory Authority (FERC) in 2014[2], the intent of this effort is generally to maintain the status quo for applicability of the standards as they have been applied over time with respect to dispersed power producing resources where the status quo does not create a reliability gap.

The SDT reviewed all standards that apply to GOs and GOPs[3] and determined how each standard requirement should be appropriately applied to dispersed power producing resources, categorized as follows:

- The existing standard language was appropriate when applied to dispersed power producing resources and does not need to be addressed;
- The existing standard language was appropriate when applied to dispersed power producing resources but additional NERC guidance documentation is needed to clarify how to implement the requirements for dispersed power producing resources; and
- The existing standard language needs to be modified in order to account for the unique characteristics of dispersed power producing resources. This could be accomplished through the a~~A~~pplicability s~~S~~ection of the standard in most cases or, if required, through narrowly~~-~~ tailored changes to the individual requirements.

From this review, the SDT determined that three (3) Reliability Standards required immediate attention to clarify the applicability of the Reliability Standards to dispersed power producing resources for the benefit of industry stakeholders. These standards are:

- PRC-004 (relevant versions)[4];
- PRC-005 (relevant versions)[5]; and
- VAR-002 (relevant versions).

The SDT recognized that many other standards[6] required further review to determine the necessity and the type of clarification or guidance for the applicability to dispersed power producing resources. This

[1] Although the BES definition uses the term "dispersed power producing resources," the SAR and the SDT also use the term "dispersed generation resources." For the purposes of this paper, these terms are interchangeable.
[2] Glossary of Terms Used in NERC Reliability Standards, updated March 12, 2014.
[3] See Appendix A.
[4] Reliability Standard PRC-004 was revised as part of Project 2010-05.1 Protection Systems: Misoperations.
[5] Reliability Standard PRC-005 was revised as part of Project 2007-17.3 – Protection System Maintenance and Testing – Phase 3.
[6] See Appendix B.

necessity is based on how each standard requirement, as written, would apply to dispersed power producing resources and the individual generating units at these facilities, considering the now currently-~~enforced~~effective BES definition. The proposed resolutions target the applicability of the standard or target specific individual requirements. There are additional methods to ensure consistent applicability throughout the Regions, including having guidance issued by NERC through Reliability Standard Audit Worksheet (RSAW) language revisions. These tools, among others, have been be considered and employed by the SDT throughout the drafting effort.

The White Paper includes: 1) description of the history of standards applicability to dispersed power producing resources; 2) identification of circumstances and practices that are unique to dispersed power producing resources; and 3) determination of the priority to address standards, supported by corresponding technical justification.

It is the intent of the SDT to modify this document over the course of this project to document the SDT's rationale and technical justification for each standard until the work of the SDT is complete. The SDT considers the sections of the White Paper that address the high-priority standards to be in final draft form. The SDT may provide further revisions to the remainder of the White Paper.

2 Purpose

The purpose of this White Paper is to provide background and technical rationale for proposed revisions to the applicability of several Reliability Standards[7] or requirements that apply to GOs and/or GOPs. The goal of the proposed applicability changes is to provide the GOs and GOPs of dispersed generation resources with clarity regarding their responsibility for requirements that impact the reliability of the BPS, as the characteristics of operating dispersed generation can be unique. The SDT seeks to provide clarity through the method most appropriate for each standard, such as by: (1) revising applicability language in the standard; (2) revising language in the requirements to address changes to applicability; (3) recommending changes to the RSAW associated with the standard; or (4) recommending a reliability guideline or reference document.

This document describes the design, operational characteristics, and unique features of dispersed power producing resources. The recommendations identified in this document consider the Purpose and Time Horizon of the standards and requirements, as well as the avoidance of applying requirements in a manner that has no significant effect on reliability.[8] This document provides justification of, and proposes revisions to, the applicability of the Reliability Standards and requirements, both existing and in development, and should be considered guidance for future standard development efforts. However, please note that the recommendations provided in this paper are subject to further review and revision.

Note that while this White Paper may provide examples of dispersed power producing resources, the concepts presented are not specific to any one technology. The SDT in general has referenced the BES Reference Document, which also refers to "dispersed power producing resources." Although the BES definition uses the term "dispersed power producing resources," the Standard Authorization Request (SAR) and the SDT also use the term "dispersed generation resources." For the purposes of this paper, these terms are interchangeable.

[7] Note that "Reliability Standard" is defined in the NERC Glossary as "approved by FERC," but that the SDT reviewed approved standards, as well as revisions to standards proposed in other projects.
[8] *North American Electric Reliability Corporation,* 138 FERC ¶ 61,193 at P 81 (2012).

3 Background

Industry stakeholders submitted a SAR to the NERC Standards Committee, requesting that the applicability of Reliability Standards or the requirements of Reliability Standards be revised to ensure that the Reliability Standards are not imposing requirements on dispersed generation resource components that are unnecessary or counterproductive to the reliability of the BPS. The SDT's focus has been to ensure that Reliability Standards are applied to dispersed power producing resources to support an effective defense-in-depth strategy and an adequate level of reliability for the interconnected BPS.

For purposes of this effort, dispersed power producing resources are those individual resources that aggregate to a total capacity greater than 75 MVA gross nameplate rating, and that are connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage of 100 kV or above. This request is related to the approved definition of the BES from Project 2010-17,[9] which resulted in the inclusion of distinct components of dispersed generation resources.

3.1 BES Definition

The BES definition[10] includes the following inclusion criterion addressing dispersed generation resources:

> *I4. Dispersed power producing resources that aggregate to a total capacity greater than 75 MVA (gross nameplate rating), and that are connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage of 100 kV or above. Thus, the facilities designated as BES are:*
>
> *a) ~~T~~the individual resources~~,~~ and*
>
> *b) ~~T~~the system designed primarily for delivering capacity from the point where those resources aggregate to greater than 75 MVA to a common point of connection at a voltage of 100 kV or above.*

The *BES Definition Reference Document*[11] includes a description of what constitutes a dispersed generation resource:

> *"Dispersed power producing resources are small-scale power generation technologies using a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include but are not limited to: solar, geothermal, energy*
>
> *storage, flywheels, wind, micro-turbines, and fuel cells."*

3.2 Dispersed Power Producing Resources

Dispersed power producing resources are often considered to be variable energy resources such as wind and solar. This description is not explicitly stated in the BES definition; however, NERC and FERC characterize variable generation in this manner regarding the purpose of Inclusion I4 of the definition.[12]. Therefore, the SDT is considering the reliability impacts of variable generation that depends on a primary fuel source ~~which~~that varies over time and cannot be stored.[13] Reliably integrating high levels of variable resources – wind, solar, ocean, and some forms of hydro – into the BPS require significant changes to traditional methods used for system planning and operation.[14] While these resources provide challenges to system operation, these resources are instrumental in meeting government-established renewable portfolio standards and requirements that are based on vital public interests.[15]

3.2.1 Design Characteristics

For dispersed power producing resources to be economically viable, it is necessary for the equipment to be geographically dispersed. The generating capacity of individual generating modules can be as small as a few hundred watts to as large as several megawatts. Factors leading to this dispersion requirement include:

- Practical maximum size for wind generators to be transported and installed at a height above ground to optimally utilize the available wind resource;
- Spacing of wind generators geographically to avoid interference between units;
- Solar panel conversion efficiency and solar resource concentration to obtain usable output; and
- Cost-effective transformation and transmission of electricity.

The utilization of small generating units results in a large number of units (e.g., several hundred wind generators or several million solar panels) installed collectively as a single facility that is connected to the Transmission system.

Dispersed power producing resources interconnected to the transmission system typically have a control system at the group level that controls voltage and power output of the Facility. The control system is capable of recognizing the capability of each individual unit or inverter to appropriately distribute the contribution required of the Facility across the available units or inverters. The variable generation control system must also recognize and account for the variation of uncontrollable factors such as wind speed and solar irradiance levels. Thus, for some standards discussed in this paper it is appropriate to apply requirements at the plant level rather than the individual generating unit.

[15] *See Rules Concerning Certification of the Electric Reliability Organization; and Procedures for the Establishment, Approval, and Enforcement of Electric Reliability Standards*, Order No. 672, FERC Stats. & Regs. ¶ 31,204, at P 335, *order on reh'g*, Order No. 672-A, FERC Stats. & Regs. ¶ 31,212 (2006).

3.2.2 Operational Characteristics

Dispersed power producing resources often rely on a variable energy source (wind, for example) that is not able to be stored. Because of this, a Facility operator cannot provide a precise forecast of the expected output to a Balancing Authority (BA), Transmission Operator (TOP) or Reliability Coordinator (RC); however, short-term forecasting capability is improving and thus reducing uncertainty.[16] The forecasting and variable operating conditions are well understood by BAs, TOPs, and RCs as evidenced by the successful operation of these generating resources over the years. Dispersed generation resources by their nature result in each individual generating unit potentially experiencing varied power system parameters (e.g. voltage, frequency, etc.) due to varied impedances and other variations in the aggregating facilities' design.

Many older dispersed power producing resources are limited in their ability to provide essential reliability services. However, due to technological improvements, newer dispersed generation resources are capable of providing system support for voltage and frequency. For efficiency, the facilities are designed to provide the system requirements at the point of interconnection to the transmission system.

3.2.3 Reliability Impact

A dispersed power producing resource is typically made up of many individual generating units. In most cases, the individual generating units are similar in design and from one manufacturer. The aggregated capability of the Facility may in some cases contribute significantly to the reliability of the BPS. As such, there can be reliability benefits from ensuring the equipment utilized to aggregate the individual units to a common point of connection are operated and maintained as required in certain applicable NERC standards. When evaluated individually, however, the individual generating units often do not provide a significant impact to BPS reliability, as the unavailability or failure of any one individual generating resource may have a negligible impact on the aggregated capability of the Facility. The SDT acknowledges that FERC addressed the question of whether individual resources should be included in the BES definition in Order Nos. 773 and 773-A and concluded that individual wind turbine generators should be included as part of the BES. The SDT is not challenging this conclusion, but rather is addressing the applicability of standards on a requirement-by-requirement basis as necessary to account for the unique characteristics of dispersed generation. Thus, the applicability of requirements to individual generating units may be unnecessary except in cases where a common mode issue exists that could lead to a loss of a significant number of units or the entire Facility in response to a transmission system event.

3.3 Drafting Team Efforts

The SDT approached this project in multiple phases. First, after a thorough discussion of the new definition of the BES, the SDT reviewed each standard, as shown in Appendix A, at a high level to recommend changes that would promote consistent applicability for dispersed power producing resources through the entire set of Reliability Standards. This review provided the type of changes proposed, the justification for the changes, and the priority of the changes. The SDT documented its review in this

[16] "*Electricity Markets and Variable Generation Integration*," WECC, January 6, 2011. https://www.wecc.biz/committees/StandingCommittees/JGC/VGS/MWG/ActivityM1/WECC%20Whitepaper%20-%20Electricity%20Markets%20and%20Variable%20Generation%20Integration.pdf

White Paper, which will continue to be updated throughout the SDT efforts. The second phase, currently in progress, includes revising standards where necessary and supporting the balloting and commenting process.

3.3.1 Scope of Standards Reviewed

Initially, the focus of the standards review was on standards and requirements applicable to GOs and GOPs. However, during discussions, a question was raised to the SDT regarding whether consideration is necessary for other requirements that affect the interaction of a Balancing Authority (BA), Transmission Operator (TOP), or Reliability Coordinator (RC) with individual BES Elements. For example, a requirement that states, "an RC shall monitor BES Elements" may unintentionally affect the RC operator due to the revised BES definition. As such, the SDT took a high-level look at all standards adopted by the NERC Board of Trustees (Board) or approved by FERC to ensure this issue was not significant.

All standards that were reviewed are listed in Appendix A along with the status of the standards as of December 11, 2014. The fields in Appendix A include the following:

- List of standards (grouped by approval status);
- Approval status of the standards (status types listed below)~~which include~~:
  - Subject to Enforcement
  - Subject to Future Enforcement
  - Filed and Pending Regulatory Approval
  - Pending Regulatory Filing
  - Designated for Retirement (~~2~~ two standards~~—-~~MOD-024-1 and MOD-025-1~~—~~ officially listed as Filed and Pending Regulatory Approval but will be superseded by MOD-025-2)
  - In Concurrent Active Development~~concurrent active development~~; and
- Indication of change or additional review necessary~~.~~

The SDT also reviewed, at a high-level, any approved regional standards. In cases where a change is recommended to a regional standard, the SDT will notify the affected Region. In addition, the SDT is prepared to provide recommendations to other active NERC standard development efforts, where appropriate.

Status	Number of Standards	Number of Standards to be Addressed (Standard, RSAW, Guidance or Further Review)
NERC Standards	**166**	**27**
Subject to Enforcement	101	12
Subject to Future Enforcement	20	5
Pending Regulatory Approval	28	4
Pending Regulatory Filing	7	0
Designated for Retirement	2	0
Proposed for Remand	8	6
Region-specific Standards (*Out of Scope)	**17**	**4**
Subject to Enforcement	15	3
Subject to Future Enforcement	2	1
Pending Regulatory Approval	0	0
Grand Total	**183**	**31**

3.3.2 Reliability Objectives

The SDT used the following ~~R~~reliability ~~O~~objectives to review the standards:

- Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC ~~Standards~~standards;
- The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand;
- Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably;
- Plans for Emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained, and implemented;
- Facilities for communication, monitoring, and control shall be provided, used, and maintained for the reliability of interconnected bulk power systems;
- Personnel responsible for planning and operating interconnected bulk power systems shall be trained~~,~~ and qualified~~,~~ and have the responsibility and authority to implement actions;
- The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis; and
- Bulk power systems shall be protected from malicious physical or cyber attacks.

3.3.3 Prioritization Methodology

The SDT established a prioritization to review and modify applicability changes recommended to NERC standards and requirements. The SDT evaluated each requirement to identify the appropriate applicability to support reliability of the BPS. In general, any standard or requirement the SDT determined to require~~d~~ modification was assigned a high, medium, or low priority. The standards and requirements priorities were established as follows:

- High priority was assigned so that standard or requirement changes would be made quickly enough to avoid an entity having to expend inordinate resources prematurely to comply with a standard or requirement that, after appropriate modification, would not be applicable to that entity;
- Medium priority was assigned if significant effort and resources with no appreciable reliability benefit would be required by an entity to be compliant~~; and~~.
- Low priority was assigned to other changes that may need to be made to further ensure requirements add to reliability, but are not perceived as a significant compliance burden.

The prioritization of each recommendation is identified in Appendix B.

- List of standards (grouped by priority);
- Approval status of the standards (same designations as used in Appendix A);
- Recommendation of changing the Applicability ~~Section~~ section of the standard or by changing the applicability for specific requirements; and
- Recommendation of which applicability options should apply.

4 Technical Discussion

This section provides a review of each group of standards, focusing on the impact of the BES definition on reliability and compliance efforts. This discussion proposes a resolution for each standard, whether it is a change in the Applicability ~~Section~~ section or in a specific requirement, clarification in a guidance document, or no action needed.

4.1 BAL

The group of BAL standards focuses primarily on ensuring the Balancing Authority (BA) has the awareness, ability, and authority to maintain the frequency and operating conditions within its Balancing Authority Area. Only two standards in this group affect GO and/or GOP, and no BAL standard reviewed affected the interaction of a host BA, TOP, or RC with individual BES Elements.

4.1.1 BAL-005 — Automatic Generation Control

The purpose of this standard, as it applies to GOPs, is to ensure that all facilities electrically synchronized to the Interconnection are included within the metered boundary of a Balancing Authority Area so that balancing of resources and demand can be achieved. Ensuring the Facility as a whole is within a Balancing Authority Area ensures the individual units are included. *Therefore, the applicability of the BAL-005 standard does not need to be changed for dispersed power producing resources.*

4.1.2 BAL-001-TRE-1 — Primary Frequency Response in the ERCOT Region

The purpose of BAL-001-TRE-1 ~~standard~~ is to maintain Interconnection steady-state frequency within defined limits. This standard should be modified to clarify the applicability for dispersed power producing resources to the total plant level to ensure coordinated performance. However, this is a regional standard and not part of the SDT scope. *The SDT will communicate this recommendation to the relevant Region.*

4.2 COM

The COM standards focus on communication between the RC, BAs, TOPs, and GOPs. The only requirements in any of the current or future enforceable standards that apply to the GOP are clearly intended to apply to the individual GOP registered functional entity (i.e., requires communication between GOPs, TOPs, BAs, and RCs), not the constituent Elements it operates. Consequently, there is no need to differentiate the GOP's obligation for dispersed power producing resources from any other resources. *Therefore, the applicability of the COM-001-2, COM-002-2a, and COM-002-4 standards that were reviewed does not need to be changed for dispersed power producing resources.*

4.3 EOP

The EOP standards focus on emergency operations and reporting. The standards that apply to GO and/or GOP entities are EOP-004 and EOP-005. No EOP standard reviewed affects the interaction of a host BA, TOP, or RC with individual BES Elements.

4.3.1 EOP-004 — Event Reporting

The purpose of this standard is to improve the reliability of the BES by requiring the reporting of events by ~~Responsible~~ responsible ~~Entities~~entities. The requirements of this standard that apply to the GO and GOP appear to apply to the individual GO and GOP registered functional entity, not the constituent elements. *The SDT has considered whether there is a need to differentiate dispersed power producing resources from any other GO and/or GOP resource and determined that no changes are required to the standard.*

4.3.2 EOP-005 — System Restoration from Blackstart Resources

EOP-005 ensures plans are in place to restore the grid from a de-energized state. The requirements that apply to a GOP are primarily for individual generation facilities designated as Blackstart Resources, with one requirement to participate in restoration exercises or simulations as requested by the RC. The inclusion of Blackstart Resources is already identified in the BES definition through Inclusion I3. The expectation is that all registered GOPs will participate in restoration exercises as requested by ~~its~~ their RC. *Therefore, the applicability of EOP-005 does not need to be changed for dispersed power producing resources.*

4.4 FAC

The FAC standards focus on establishing ratings and limits of the Facility and interconnection requirements to the BES. Several standards apply to GOs and/or GOPs. No FAC standard reviewed affects the interaction of a host BA, TOP, or RC with individual BES Elements.

4.4.1 FAC-001 — Facility Connection Requirements

Requirements R2 and R3 of this standard apply to any GO that has an external party applying for interconnection to the GO's existing Facility in order to connect to the transmission system. This scenario is uncommon and there is no precedent for applicability of this standard to dispersed power producing resources known to the SDT. Current practice primarily includes the GO stating that they will comply with the standard if this scenario is ever realized. This standard allows the GO to specify the conditions that must be met for the interconnection of the third-party, thus providing inherent flexibility to tailor the requirements specifically for the unique needs of the Facility. *Therefore, the applicability of FAC-001 does not need to be changed for dispersed power producing resources.*

4.4.2 FAC-002 — Coordination of Plans for New Facilities

The purpose of FAC-002 is to ensure coordinated assessments of new facilities. The requirement applicable to GOs requires coordination and cooperation on assessments to demonstrate the impact of new facilities on the interconnected system and to demonstrate compliance with NERC standards and other applicable requirements. The methods used to demonstrate compliance are independent of the type of generation and are typically completed at the point of interconnection. *Therefore, the applicability of FAC-002 does not need to be changed for dispersed power producing resources.*

4.4.3 FAC-003 — Transmission Vegetation Management

The purpose of this standard is to ensure programs and efforts are in place to prevent vegetation-related outages. This standard applies equally to dispersed generation facilities and traditional Facilities in both applicability and current practices, as it pertains to overhead transmission lines of applicable generation

interconnection Facilities. *Therefore, the applicability of FAC-003 does not need to be changed for dispersed power producing resources.*

4.4.4 FAC-008 — Facility Ratings

FAC-008 ensures Facility ratings used in the planning and operation of the BES are established and communicated. The Facility ratings requirement has historically been applicable to dispersed power producing resources and current practices associated with compliance are similar to traditional generation facilities. There is inherent flexibility in the standard requirements for the GO to determine the methodology utilized in determining the Facility ratings.

To identify the Facility rating of a dispersed power producing resource the analysis of the entire suite of Facility components is necessary to adequately identify the minimum and maximum Facility Rating and System Operating Limits, and thus there would be no differentiation between the compliance obligations between dispersed power producing resources and traditional generation. *The SDT believes the industry and Regions would benefit from additional guidance on FAC-008 in the form of ~~changes to add a~~ the technical guidance ~~section to the standard, or other guidance~~provided below.*

Guidelines and Technical Basis

FAC-008 ensures facility ratings used in the planning and operation of the BES are established and communicated. The facility ratings requirement has historically been applicable to dispersed power producing resources and current practices associated with compliance are similar to traditional generation facilities. There is inherent flexibility in the standard requirements for the GO to determine the methodology utilized in determining the facility ratings.

To identify the facility rating of a dispersed power producing resource the analysis of the entire suite of facility components is necessary to adequately identify the minimum and maximum Facility Rating and System Operating Limits, and thus there would be no differentiation between the compliance obligations between dispersed power producing resources and traditional generation.

The use of the term "main step-up transformer" in Requirements R1 and R2 refers to the final GSU (the last transformer(s) used exclusively for stepping up the generator output) prior to the point of interconnection or, when the point of interconnection is before the GSU, the GSU that steps up voltage to transmission line voltage level and is used strictly as a delineation point between Requirements R1 and R2. In an attempt to address this potential misinterpretation, the SDT provides the following clarifications:

1. Referencing the NERC Glossary definition of Facility Ratings~~,~~ identifies that the voltage, current, frequency, and real or reactive power flow through a facility must not violate the equipment rating of any equipment of the facility (that is subjected to the voltage, current, etc.). With this definition, it is clear that each component or piece of equipment must be reviewed to ensure the ratings are not exceeded, and that applicable documentation be maintained.
2. The use of the term "Facilities" in the phrase "…determining the Facility Ratings of its solely and jointly owned generator Facility(ies) up to the low side terminals of the main step up transformer…" could potentially be interpreted to refer only to BES Facilities because the Glossary definition of "Facility" includes the term "Bulk Electric System Element." For dispersed power producing facilities, that could leave out portions of the facility, specifically the collection system. However, the intent of the standard is to address the Facility Ratings of all electrical equipment from the generator to the point of interconnection.

As an example, for solar facilities, a GO or GOP should provide ratings for array or panel, DC Cables (Positive and Negative), combiner boxes, inverters, as well as associated breakers, instrument transformers (CVTs, PTs), disconnect switches, and relays, etc. This is shown in Figure A.

If there are multiple sample units, comprised of a multiple of identical components with identical ratings, then only one sample unit must be provided for that piece of equipment when calculating the facility rating value. For example, if a facility is comprised of 50 identical inverter units rated at 2 MW that have identical combiner box, module string and module compositions/orientations, then the Facility rating would be 50*2 MW = 100 MW.

In order to identify the most limiting component of the facility, a complete analysis of every component in a sample unit must be conducted. Under the assumption that the GO owns the main step-up transformer, this will include analysis from the generator (solar module or WTG) up through the high side terminals of the main step-up transformer. In an effort to simplify this analysis, grouping identical equipment configurations into a sample unit is an accepted industry practice. The following discussion and diagrams provide an explanation of how this could be accomplished for dispersed power producing resources (wind and solar).

Figure A Walk-through: For each sample unit identified, it should be clarified that a thorough rating analysis of each sample unit component must be conducted at least once to identify any potential limiting component and determine the sample unit rating. Upon completion of this analysis and arrival at a rating value, future representations of the sample unit would then be able to utilize this calculated sample unit rating as opposed to reiterating the individual component analysis.

Sample Unit #1: This sample unit is comprised of the 250W solar modules, combiner box "A", conductors and other electrical equipment from the solar module to, but not including, the inverter. This sample unit encompasses three strings. In order to be referenced as a sample unit in future occurrences, this exact configuration must be met (3 strings, same type and number of modules, same conductor type and configuration, and same electrical components).

Sample Unit #2: This sample unit is limited to an individual string and its components (eight 250 W modules and conductors) up to the combiner box "B." The middle string (without dotted line) associated with combiner box B is actually a second instance of the Sample Unit #2 and thus would not need a separate rating analysis and would instead be represented as a multiple of Sample Unit #2 in the overall rating analysis.

Sample Unit #3: This sample unit is also limited to a single string and its components up to combiner box B. While this string utilizes the same type of solar module (250 W) as Sample Unit #2, there are fewer modules in this string, which differentiates this string from Sample Unit #2 and thus requires this string to be represented separately.
Note that combiner box B is not included in either Sample Unit #2 or #3 and thus would need to be rated separately.

Sample Unit #4: This sample unit is limited to an individual string and its components (eight 300 W modules and conductors) up to the combiner box "C." The upper string (without dotted line) associated with combiner box C is actually a third instance of the Sample Unit #2. The lower string (without dotted line) associated with combiner box C is actually a second instance of the sample unit #4. Note that combiner box C is not included in any sample unit and thus would need to be rated separately.

Sample Unit #5: This sample unit is similar to the sample unit #1 configuration but utilizes 300W modules instead of 250W modules thus would need a separate rating analysis.

Sample Unit #6: This sample unit represents all the components and sample units leading up to, and including, the inverter. The lower right-hand section of Figure A shows that the inverter that comprises these various sample units is one of four identical units that feed into a substation bus. Thus, since the rating of this inverter has been identified as 80 kW (from manufacturer) and all the components have previously been thoroughly analyzed, the other three identical units can be represented as other instances of sample unit #6.

Sample Unit #7: This sample unit represents an inverter and/or component configuration that is different from sample unit #6. This scenario, in which the inverter in this sample unit is identical to the inverter utilized in sample unit #6, but the underlying component configuration is different from in sample unit #6 necessitates representation of this sample unit separately from Sample Unit #6.

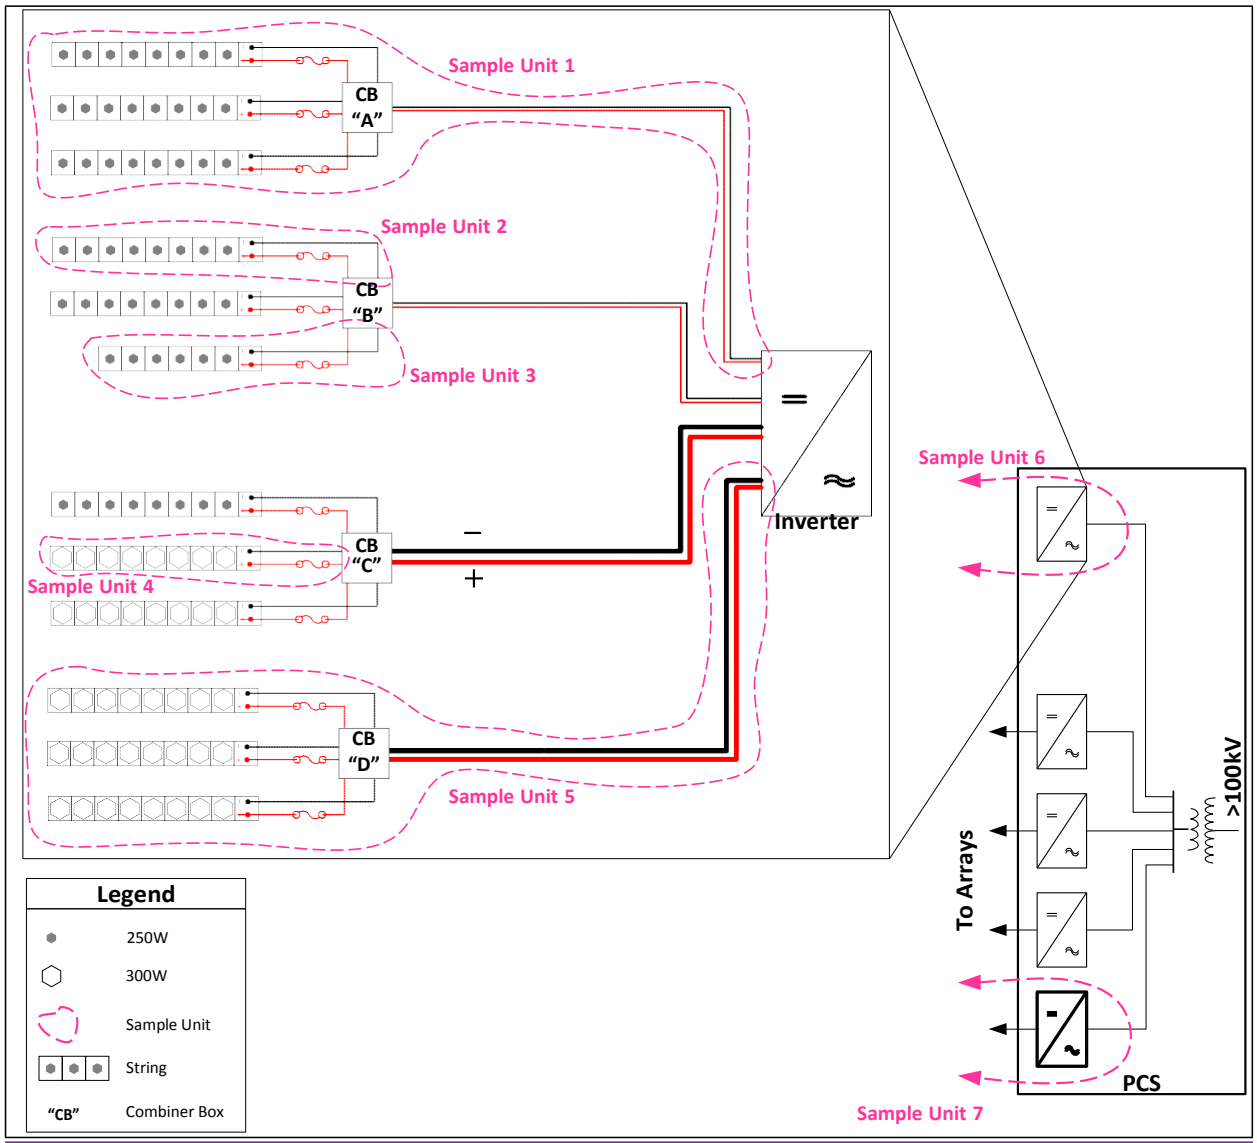

Figure A: Sample Unit Representation (Solar)

Once a complete analysis of the sample unit is conducted, this sample unit can then be referred to in future rating analyses without repeating the complete sample unit analysis. This scenario is illustrated in Table A below.

Table A:

Element	Unit Rating	#Units in system	Rating
Sample Unit #1 (Nine strings of eight 250 W modules each)	18 kW	1	18 kW
Sample Unit #2 (Three strings of eight 250 W modules)	6 kW	3	18 kW
Sample Unit #3 (Three Strings of six 250 W modules)	4.5 kW	1	4.5 kW
Sample Unit #4 (Three strings of six 300 W modules)	5.4 kW	2	10.8 kW
Sample Unit #5 (Nine strings of eight 300 W modules each)	21.6 kW	1	21.6 kW
Sample Unit #6	80 kW	4	320 kW
Sample Unit #7	80 kW	1	80 kW

Figure B Walk-through: For each sample unit identified, it should be clarified that a thorough rating analysis of each sample unit component and all other serial components through to the point of interconnection must be conducted once to identify any potential limiting component and determine the sample unit rating. Upon completion of this analysis and arrival at a rating value, future representations of the sample unit would then be able to utilize this calculated sample unit rating as opposed to reiterating the individual component analysis.

Sample Unit #1: This sample unit is comprised of the Manufacturer "A" wind turbines (WTG) rated at 2.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of four WTGs. In order to be referenced as a sample unit in future occurrences, this exact configuration must be met (same type and number of WTGs, same step-up transformer, same conductor type and configuration, and same electrical components).

Sample Unit #2: This sample unit is comprised of the Manufacturer "A" wind turbines (WTG) rated at 2.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of six WTGs. The different number of WTGs in this string versus those in the sample unit #1 necessitates a separate consideration from the sample unit #1.

Sample Unit #3: This sample unit is comprised of the Manufacturer "B" wind turbines (WTG) rated at 3.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of four WTGs.

Sample Unit #4: This sample unit is comprised of the Manufacturer "B" wind turbines (WTG) rated at 3.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of six WTGs. The different number of WTGs in this string versus those in the sample unit #3 necessitates a separate consideration from the sample unit #3.

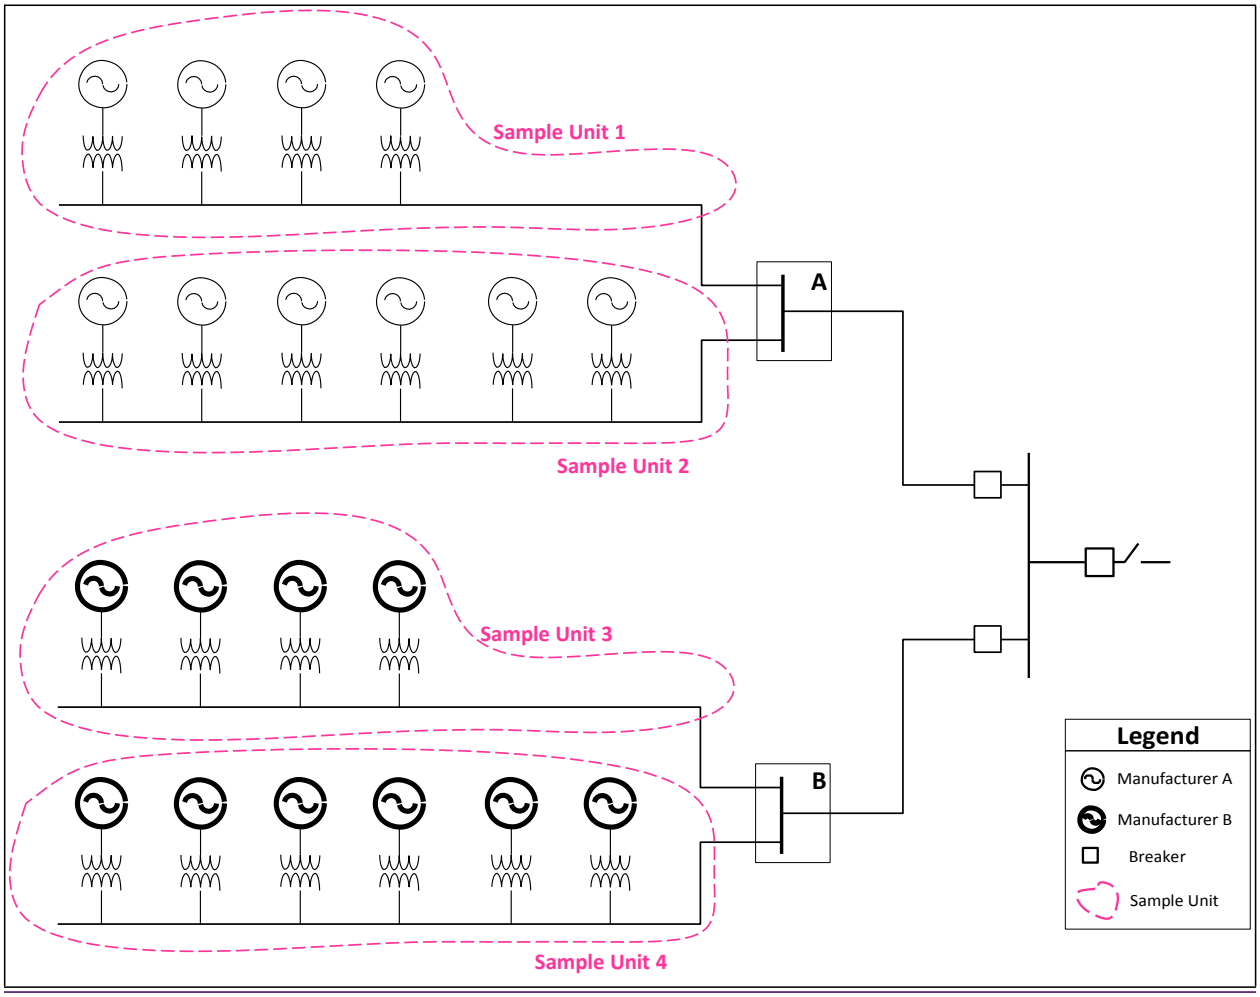

Figure B: Sample Unit Representation (Wind)

4.5 INT

The INT standards provide BAs the authority to monitor power interchange between Balancing Authority Areas. No INT standard is applicable to the GO or GOP, or affects the interaction of a host BA, TOP, or RC with individual BES Elements. *Therefore, the applicability of the INT standards does not need to be changed for dispersed power producing resources.*

4.6 IRO

The IRO standards provide RCs their authority. ~~There are t~~three IRO ~~Standards~~ standards that apply directly to GO and/or GOP entities. ~~There are t~~three standards ~~that~~ apply to the interaction of the RC with individual BES Elements. No other IRO standard reviewed affected the interaction of a host BA, TOP, or RC with GOs and/or GOPs.

4.6.1 IRO-001 — Reliability Coordination — Responsibilities and Authorities[17]

The purpose of these standards and their requirements as applicable to a GOP is to ensure RC directives are complied with so long as they do not violate safety, equipment, or regulatory or statutory requirements, or cannot be physically implemented. If a GOP is unable to follow an RC directive, ~~they are~~it is to inform the RC immediately ~~of such~~.

Directives from RCs have been traditionally applied to the dispersed power producing resource at the aggregate Facility level when they are related to either active power or voltage, such as an output reduction or the provision of voltage support. When such directives are not specific to any one Element within the Facility, it is up to the GOP to determine the appropriate method to achieve the desired result of the directive consistent with other applicable NERC Reliability Standards. When an RC directive specifies a particular Element or Elements at the GOP's Facility, it is the expectation and requirement that the GOP will act as directed, so long as doing so does not violate safety, equipment, or regulatory or statutory requirements or cannot be physically implemented. For example, a directive could specify operation of a particular circuit breaker at a GOP Facility. *For these reasons, the applicability of IRO-001 does not need to be changed for dispersed power producing resources.*

4.6.2 IRO-005 — Reliability Coordination — Current Day Operations[18]

The purpose of this standard and its requirements as ~~it~~ they relate~~s~~ to GOPs is to ensure that when there is a difference in derived limits, the BES is operated to the most limiting parameter. A difference in derived limits can occur on any Element; ~~and~~ therefore, any limitation of the applicability of this standard may create a reliability gap. There is no need to differentiate applicability to dispersed generation resources from any other GOP resources. *Therefore, the applicability of IRO-005 does not need to be changed for dispersed power producing resources.*

[17] Note that IRO-001-3, which is adopted by the Board, was included in the proposed remand by FERC and is subject to revision as part of Project 2014-3 – Revisions to TOP and IRO Standards.

[18] Note that applicability to GOPs has been removed in IRO-005-4, which is adopted by the Board. However, this standard was included in the proposed remand by FERC and is subject to revision as part of Project 2014-3 – Revisions to TOP and IRO Standards.

4.6.3 IRO-010 — Reliability Coordinator Data Specification and Collection

The purpose of this standard and its requirement(s) as it relates to GOs and GOPs is to ensure data and information specified by the RC is provided. As each RC area is different in nature, up to and including the tools used to ensure the reliability of the BPS, a ~~'~~one ~~-~~size ~~-~~fits ~~-~~all~~'~~ approach is not appropriate. This Reliability Standard allows ~~for~~ the RC to specify the data and information required from the GO and/or the GOP, based on what is required to support the reliability of the BPS. *Therefore, the applicability of IRO-010 does not need to be changed for dispersed power producing resources.*

4.7 MOD

The MOD ~~group of~~ standards ensure~~s~~ consistent modeling data requirements and reporting procedures. The MOD standards provide a path for Transmission Planners (TPs) and Planning Coordinators (PCs) to reach out to entities for specific modeling information, if required. The SDT believes the existing and proposed modeling standards are sufficient for modeling dispersed power producing resources. However, due to the unique nature of dispersed power producing resources and an effort to bring consistency to the models, *the SDT believes additional guidance on the MOD standards would be beneficial and will communicate its determination to the NERC Planning Committee.*

4.7.1 MOD-010 — Steady-State Data for Transmission System Modeling and Simulation

This standard is anticipated to be retired in the near future. There is no need to differentiate dispersed generation resources from any other GOP resources as discussed in 5.7.8 regarding MOD-032. *Therefore, the applicability of MOD-010 does not need to be changed for dispersed generation resources.*

4.7.2 MOD-012 — Dynamics Data for Transmission System Modeling and Simulation

This standard is anticipated to be retired in the near future. There is no need to differentiate dispersed generation resources from any other GOP resources as discussed in 5.7.8 regarding MOD-032. *Therefore, the applicability of MOD-012 does not need to be changed for dispersed generation resources.*

4.7.3 MOD-024-1 — Verification of Generator Gross and Net Real Power Capability

This standard was established to ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess BES reliability. This standard will be superseded by MOD-025-2.[19] *Therefore, the applicability of MOD-024-1 does not need to be changed for dispersed generation resources.*

4.7.4 MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability

This standard was established to ensure accurate information on generator gross and net Reactive Power capability is available for steady-state models used to assess BES reliability. This standard will be superseded by MOD-025-2. *Therefore, the applicability of MOD-025-1 does not need to be changed for dispersed generation resources.*

[19] MOD-024-1 and MOD-025-1 are Board ~~Adopted~~ adopted but not subject to enforcement. They are commonly followed as good utility practice.

4.7.5 MOD-025-2 — Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

The purpose of MOD-025-2 is to ensure that accurate information on generator gross and net Real and Reactive Power capability is available for planning models used to assess BES reliability. This standard is appropriate for and includes specific provisions for dispersed generation resources to ensure changes in capabilities are reported. *Therefore, the SDT is further evaluating whether to revise the applicability of the standard to align the language with the revised BES definition.*

4.7.6 MOD-026 — Verification of Models and Data for Generator Excitation Control System or Plant Volt/VAR Control Functions

This standard provides for verification of models and data for voltage control functions. This standard is appropriate for dispersed generation resources. *Originally, the DGR SDT considered clarifying the applicability of the Facilities section; however, upon further review, the DGR SDT recommends no change.*

4.7.7 MOD-027 — Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

This standard was established to verify that the turbine/governor and frequency control model accurately represents generator unit Real Power response to system frequency variations. This standard is appropriate for dispersed generation resources. *Originally, the DGR SDT considered clarifying the applicability of ~~–~~the Facilities section~~;~~ however, upon further review, the DGR SDT recommends no change.*

4.7.8 MOD-032 — Data for Power System Modeling and Analysis

The MOD-032 standard was established to ensure consistent modeling data requirements and reporting procedures for the planning horizon cases. The nature of dispersed generation resources is a challenge in modeling the steady-state and dynamic electrical properties of the individual components (e.g., individual units, collector system, interconnection components, etc.).

Models for dispersed power producing resources are typically proprietary and unique for each Facility. Generic models exist for dynamic analysis that may provide sufficient accuracy in lieu of a Facility-specific model. Some sections of ~~the~~ MOD-032 Attachment 1 pertain to modeling individual units, which may not be feasible. Guidance should be provided to show how to best model dispersed power producing resources. Such guidance should require modeling requirements for each type of dispersed power producing resource within a Facility and aggregate model for each reasonable aggregation point. *The applicability of MOD-032 does not need to be changed for dispersed power producing resources.*

4.8 NUC

The requirements in standard NUC-001~~—~~, Nuclear Plant Interface Coordination, individually define the applicability to ~~Registered~~ registered ~~Entities~~entities, not to the Elements the entities own or operate. While it is unlikely any Elements that are part of a dispersed power producing resource would be subject to an agreement required by this standard, limiting the applicability of this standard could create a reliability gap, and thus~~,~~ there is no need to differentiate applicability to dispersed generation resources. *Therefore, the applicability of the NUC standard does not need to be changed for dispersed power producing resources.*

4.9 PER

The PER standards focus on operator personnel training. The only requirements in any of the current or future enforceable standards that apply to the GOP is requirement R6 in PER-005-2—, Operations Personnel Training, and it is clearly intended to apply to the individual GOP registered functional entity that controls a fleet of generating facilities, not the constituent Elements it operates. As such, there is no need to differentiate dispersed power producing resources from any other GOP resources. *Therefore, the applicability of the PER standards do not need to be changed for dispersed power producing resources.*

4.10 PRC

The PRC standards establish guidance to ensure appropriate protection is established to protect the BES.

4.10.1 PRC-001-1.1 — System Protection Coordination

Requirement R1 requires GOPs to be familiar with the purpose and limitations of Protection System schemes applied in their area. The recently approved changes to the BES definition extend the applicability of this requirement. Often this familiarity is provided to GOP personnel through training on the basic concepts of relay protection and how it is utilized. The basic relaying concepts utilized in protection on the aggregating equipment at a dispersed generation site typically will not vary significantly from the concepts used in Protection Systems on individual generating units.

Requirement R2 requires that GOPs report protective relay or equipment failures that reduce system reliability. Protective System failures occurring within a single individual generating unit at a dispersed power producing resource will not have any impact on overall system reliability, and thus it should not be necessary for GOPs to report these failures to their TOPs and host BAs. Only failures of Protection Systems on aggregating equipment have the potential to impact BPS reliability and may require notification. When interpreted as stated above, no related changes should be required to the existing PRC-001-1 standard, as the BES definition changes do not have an impact on these requirements.

Requirement R3 requires GOPs to coordinate new protective systems. Coordinating new, and changes to existing, protective relay schemes should be applied to aggregating equipment protection only if a lack of coordination could cause unintended operation or non-operation of an interconnected entity's protection, thus potentially having an adverse impact to the BPS. Existing industry practice is to share/coordinate the protective relay settings on the point of interconnect (e.g., generator leads, radial generator tie-line, etc.) and potentially the main step-up transformer, but not operating (collection) buses, collection feeders, or individual generator protection schemes, as these Protection Systems do not directly coordinate with an interconnected utility's own Protection Systems. Relay protection functions such as under- and ~~overfrequency~~ over frequency and under- and overvoltage changes are independent of the interconnected utility's protective relay settings, and the setting criteria are defined in PRC-024.

Requirement R5 requires GOPs to coordinate changes in generation, transmission, load, or operating conditions that could require changes in the Protection Systems of others. A GOP of a dispersed generation resource should be required to notify its TOP of changes to generation, transmission, load, or operating conditions on an aggregate Facility level.

Project 2007-06 – System Protection Coordination and Project 2014-03 – Revisions to TOP and IRO Standards are presently revising various aspects of this standard or addressing certain requirements in other standards.

For these reasons, the DGR SDT coordinated with the other SDTs currently reviewing this standard and recommended revisions to Requirement R3.1 to indicate that coordination by a GOP with ~~their~~ its TOP and host BA of new, or changes to, protection systems on individual generating units of dispersed power producing resources is not required.

4.10.2 PRC-001-2 — System Protection Coordination

The concerns addressed with PRC-001-1.1b are removed in PRC-001-2, which is adopted by the Board. However, this standard was included in the proposed remand by FERC and is subject to revision as part of Project 2014-03 – Revisions to TOP and IRO Standards. This ~~S~~standard version is not in effect and was withdrawn as the proposed versions of the TOP and IRO Reliability Standards included in Project 2014-3 effectively replace PRC-001-2 and other TOP standards. *For this reason, no changes are required.*

4.10.3 PRC-002-NPCC-01— Disturbance Monitoring
PRC-018-1 — Disturbance Monitoring Equipment Installation and Data Reporting

Requirements related to installation of Fault/Disturbance monitoring and/or sequence of events (SOE) recording capabilities on generating units and substation equipment which meet regional specific criteria may require installation of these capabilities on the aggregating equipment at a dispersed power producing resource Facility, and ~~also~~ requires maintenance and periodic reporting requirements to their RRO. However, these requirements have been previously applicable to the aggregating equipment at these dispersed power producing resources, and these capabilities are not required to be installed on the individual generating units. The BES definition changes have no direct impact on applicability of these standards to dispersed power producing resources. *Therefore, the applicability of these standards do*es *not need to be changed for dispersed power producing resources.*[20]

4.10.4 PRC-004-2.1a – Analysis and Mitigation of Transmission and Generation Protection System Misoperations
PRC-004-3 — Protection System Misoperation Identification and Correction

Misoperation reporting per PRC-004 is currently a requirement applied on the aggregating equipment at applicable dispersed power producing resource sites that meet~~ing~~ BPS criteria. The continuation of this analysis and reporting on the aggregating equipment by dispersed generation resource owners can provide value to BPS reliability and should remain in place. However, based on the experience of the SDT, there is minimal impact to BPS reliability for analyzing, reporting, and developing Corrective Action Plans for each individual generating unit that trips at a dispersed power producing resource site, as the tripping of one or a small number of these units has no material impact to ~~the~~ BPS reliability.

Additionally, reporting of Misoperations on each individual generating unit may result in substantial and unnecessary burdens on both the dispersed generation resource owner and the Regional Entities that review and track the resulting reports and Corrective Action Plan implementations. The SDT recognizes that many turbine technologies do not have the design capability of providing sufficient data for an entity

[20] *See* NPCC CGS-005.

to evaluate whether a Misoperation has occurred. Furthermore, dispersed power producing resources by their nature result in each individual generating unit potentially experiencing varied power system parameters (e.g., voltage, frequency, etc.) due to varied impedances and other variations in the aggregating facilities design. This limits the ability to determine whether an individual unit correctly responded to a system disturbance.

However, the SDT maintains that Misoperations occurring on the Protection Systems of individual generation resources identified under Inclusion I4 of the BES definition do not have a material impact on BES reliability when considered individually; however, the aggregate capability of these resources may impact BES reliability if a large number of the individual generation resources (aggregate nameplate rating of greater than 75 MVA) incorrectly operated or failed to operate as designed during a system event. As such, if a trip aggregating to greater than 75 MVA occurs in response to a system disturbance, the SDT proposed requiring analysis and reporting of Misoperations of individual generating units for which the root cause of the Protection System operation(s) affected an aggregate rating of greater than 75 MVA of BES Facilities. Note that the SDT selected the 75 MVA nameplate threshold for consistency and to prevent confusion.

The SDT was also concerned with the applicability of events where one or more individual units tripped and the root cause of the operations was identified as a setting error. In this case, the requirements of PRC-004 would be applicable for any individual units where identical settings were applied on the Protection Systems of like individual generation resources identified under Inclusion I4 of the BES definition.

The SDT concluded that it is not necessary under PRC-004 to analyze each individual Protection System Misoperation affecting individual generating units of a dispersed power producing resource. *The SDT recommended changes to the applicability of this standard to require misoperation analysis on individual generating units at a dispersed power producing resource site, only for events affecting greater than 75MVA aggregate nameplate; the SDT determined that this will ensure that common--mode failure scenarios and their potential impact on BPS reliability are appropriately addressed. The SDT's recommended changes passed industry ballot on November 6, 2014, ~~and~~ were approved by the Board on November 13, 2014, and are currently pending regulatory approval.*

4.10.5 PRC-004-WECC-1 — Protection System and Remedial Action Scheme Misoperation

Dispersed power producing resource sites typically would not be associated with a WECC Major Transfer Path or Remedial Action Scheme (RAS), and thus would not be affected by PRC-004-WECC-1. If a site were to be involved with one of these paths or schemes, it is likely that associated protection or RAS equipment would be located on the aggregating equipment rather than the individual generating units. As such, the BES definition changes may have an impact on applicability of this standard to dispersed power producing resources. This standard should be modified to clarify the applicability for dispersed generation resources; however, this is a regional standard and not part of the SDT's scope. *Therefore, the SDT recommends that the relevant Region evaluate the standard for modification.*

4.10.6 PRC-005-1.1b — Transmission and Generation Protection System Maintenance and Testing

The SDT recognizes that PRC-005-1.1b will be phased out beginning in early 2015. Therefore, the SDT recommends only guidance on PRC-005-1.1b rather than suggesting language changes to the standard. *Therefore, the SDT does not recommend revising the applicability of this standard for dispersed generation resources~~,~~. ~~rather~~Rather, the SDT provided recommendations for revisions to the applicable RSAW to NERC staff, which NERC has implemented after consultation with the Regions.*

4.10.7 PRC-005-2 — Protection System Maintenance
PRC-005-3 — Protection System and Automatic Reclosing Maintenance
PRC-005-4 — Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance

~~The~~In some cases, the aggregated capability of the individual generating units may ~~in some cases~~ contribute to the reliability of the BPS; as such, there can be reliability benefit from ensuring that certain BES equipment utilized to aggregate the individual units to a common point of connection are operated and maintained as required in PRC-005. When evaluated individually, however, the generating units themselves do not have the same impact on BPS reliability as the system used to aggregate the units. The unavailability or failure of any one individual generating unit would have a negligible impact on the aggregated capability of the Facility; this would be irrespective to whether the dispersed generation resource became unavailable due to occurrence of a legitimate fault condition or due to a failure of a control system, protective element, dc supply, etc.

The protection typically utilized in these generating units includes elements ~~which~~that would automatically remove the individual unit from service for certain internal or external conditions, including an internal fault in the unit. These units typically are designed to provide generation output at low voltage levels~~,~~ (i.e., less than 1000 V). Should these protection elements fail to remove the generating unit for this scenario, the impacts would be limited to the loss of the individual generating unit and potentially the next device upstream in the collection system of the dispersed power producing resource. However, this would still only result in the loss of a portion of the aggregated capability of the Facility, which would be equally likely to occur due to a scenario in which a fault occurs on the collection system.

Internal faults on the low~~-~~voltage system of these generating units would not be discernible on the interconnected transmission systems, as this is similar to a fault occurring on a typical utility distribution system fed from a substation designed to serve customer load. It is important to note that the collection system equipment (e.g., breakers, relays, etc.) used to aggregate the individual units may be relied upon to clear the fault condition in both of the above scenarios, which further justifies ensuring portions of the BES collection equipment is maintained appropriately.

For this reason, activities such as Protection System maintenance on each individual generating unit at a dispersed generation Facility would not provide any additional reliability benefits to the BPS, but Protection System maintenance on facilities where generation aggregates to 75 MVA or more would. The SDT proposes that the scope of PRC-005 be limited to include only the protection systems that operate at a point of aggregation above 75 MVA nameplate rating. If the aggregation point occurs at a component in the collection system, then the protection systems associated with this component would be in scope. *The SDT has recommended changes to the Applicability Section (Facilities) of PRC-005-2, -3, and -4 to indicate that maintenance activities should only apply on the aggregating equipment at or above the point where the aggregation exceeds 75 MVA. The Board approved the SDT's recommended applicability changes to PRC-005-2 and PRC-005-3 ~~were approved by the Board~~ on November 13, 2014. The SDT's recommended applicability changes to PRC-005-4 ~~were posted for an initial ballot period that ends on January 22, 2014.~~are pending Board approval.*

4.10.8 PRC-006-NPCC-1 — Automatic Underfrequency Load Shedding PRC-006-SERC -1 — Automatic Underfrequency Load Shedding Requirements

The regional specific PRC-006 standards deviate from the PRC-006-1 standard in that they have specific requirements for GOs. In particular, the NPCC version requires that GOs set their underfrequency tripping to meet certain criteria to ensure reliability of the BPS. Typically, a dispersed generation resource site may have underfrequency protection on both the aggregating equipment (i.e., collection buses or feeders) ~~as well as~~ and the individual generating units. ~~Were~~ If this standard were only to apply to aggregating equipment, the net impact to the BPS should a system disturbance occur may still result in a loss of significant generating capacity ~~should~~ if each of the individual generating units trip for the event.

Therefore, it may be appropriate to include the individual generating units at a dispersed generation resource site as subject to this standard. The standard could be interpreted this way as written, but further clarification in the standard language may be considered. While this standard may need to be modified to clarify the applicability for dispersed generation resources, this is a regional standard and not part of the SDT's scope. *Therefore, the SDT recommends that the relevant Region evaluate the standard for modification.*

The SERC version of PRC-006 requires GOs to provide, upon request, certain under and overfrequency related set points and other related capabilities of the site relative to system disturbances. It may be appropriate to include the capabilities of the individual generating units at a dispersed generation resource site when providing this information; however, it may be sufficient to provide only the capabilities of a single sample unit within a site, as these units are typically set identically. This would be in addition to any related capabilities or limitations of the aggregating equipment as well. This may be accomplished by providing clarifications in the requirements sections. While this standard may need to be modified to clarify the applicability for dispersed power producing resources, this is a regional standard and not part of the SDT's scope. *Therefore, the SDT recommends that the relevant Region evaluate the standard for modification.*

4.10.9 PRC-015 — Special Protection System Data and Documentation
PRC-016 — Special Protection System Misoperations
PRC-017 — Special Protection System Maintenance and Testing

Relatively few dispersed power producing resources own or operate Special Protection Systems (SPSs); however, they do exist and therefore need to be evaluated for applicability based on the revised BES definition. The vast majority of these SPSs involve the aggregating equipment (transformers, collection breakers, etc.) and not the individual generating units. The SPSs are installed to protect the reliability of the BPS, and as such the aggregated response of the site (e.g., reduction in output, complete disconnection from the BES, etc.) is critical, not the response of individual generating units. *Therefore, the applicability of these standards does not need to be changed for dispersed power producing resources.*

4.10.10 PRC-019-1 — Coordination of Generating Unit or Plant Capabilities, Voltage Regulating Controls, and Protection

Dispersed power producing resources typically utilize a site-level voltage control scheme that directs the individual generating units to adjust their output to meet the voltage requirements at an aggregate Facility level. In these cases, the individual generating units will simply no longer respond once they are "maxed out" in providing voltage or reactive changes, but also need to be properly coordinated with protection – trip settings on the aggregating equipment to mitigate the risk of tripping in this scenario. For those facilities that solely regulate voltage at the individual unit, these facilities also need to consider the Protection Systems at the individual units and their compatibility with the reactive and voltage limitations of the units. The applicability in PRC-019-1 (section 4.2.3) includes a "Generating plant/Facility consisting of one or more units that are connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate nameplate rating)." *Therefore, the DGR SDT revised the Facilities section of the standard to clarify that facilities which solely regulate voltage at the individual generating unit are subject to this standard's requirements. The SDT's recommended applicability changes to PRC-019-1 were posted for an initial comment and ballot period scheduled to close December 22, 2014filed with FERC March 13, 2015.*

4.10.11 PRC-023— Transmission Relay Loadability

Dispersed power producing resources in some cases contain facilities and Protection Systems that meet the criteria described in the Applicability Section section (e.g., load-responsive phase Protection System on transmission lines operated at 200 kV or above); however, in the majority of cases these lines are radially connected to the remainder of the BES and are excluded from the standard requirements of PRC-023-3. While certain entities with dispersed power producing resources are required to meet the requirements of PRC-023 on components of their aggregating equipment (e.g., main step-up transformers, interconnecting transmission lines), the standard is not applicable to the individual generating units, as the individual generating units are addressed in PRC-025. The BES definition changes have no direct impact on the applicability of this standard to dispersed power producing resources. *Therefore, the applicability of this standard does not need to be changed for dispersed power producing resources.*

4.10.12 PRC-024— Generator Frequency and Voltage Protective Relay Settings

If the individual generating units at a dispersed power producing resource were excluded from this requirement, it is possible large portions or perhaps the entire output of a dispersed power producing

resource site may be lost during certain system disturbances, negatively impacting BES reliability. The SDT has determined it is appropriate to require that ~~Protection System~~protective relay settings applied on both the individual generating units and aggregating equipment (including any ~~Protection Systems applied on non-BES portions of the aggregating~~non-BES collection system equipment~~),~~) are set ~~within~~ respecting the "no-trip zone" referenced in the requirements to maintain reliability of the BES. However, for the purpose of compliance evidence, the SDT believes it should be sufficient for an entity to provide evidence for a single sample generating unit within a site rather than providing documentation for each individual unit, providing the entity used that methodology to set its protection systems for all the units, rather than providing documentation for each individual unit. This would be in addition to any Protection System settings evidence for the aggregating equipment. *The SDT therefore recommended changes to the standard requirements to ensure these requirements are applied to the individual power producing resources as well as all equipment, potentially including non-BES equipment, from the individual power producing resource up to the point of interconnection and communicated compliance evidence requirement considerations to NERC staff for RSAW development. The SDT's recommended applicability changes to PRC-024 were ~~posted for an initial comment and ballot period scheduled to close December 22, 2014~~filed with FERC March 13, 2015.*

4.10.13 PRC-025— Generator Relay Loadability

The Protection System utilized on individual generating units at a dispersed power producing Facility may include load-responsive protective relays and thus would be subject to the settings requirements listed in this standard. Were this standard only to apply to aggregating equipment, the net impact to the BPS ~~should~~ if a system disturbance were to occur~~,~~ may be a loss of significant generating capacity ~~should~~ if each of the individual generating units trips for the event. The SDT has determined it is appropriate to require that Protection System settings be applied on both the individual generating units at a dispersed power producing resource site as applicable to this standard. However, for the purpose of compliance evidence, the SDT believes it should be sufficient for an entity to provide evidence for a single sample generating unit within a site rather than providing documentation for each individual unit, providing the entity used that methodology to set its protection systems for all the units, rather than providing documentation for each individual unit. This would be in addition to any Protection System settings evidence for the aggregating equipment. As such, the SDT recommends the RSAW be modified as stated above. *The SDT recommended no changes to the standard; however, the DGR SDT communicated compliance evidence requirement considerations to NERC staff for RSAW development.*

4.11 TOP

The TOP standards provide TOPs their authority. ~~There are f~~Four TOP standards ~~that~~ apply directly to GO and GOP entities. The TOP standards as they relate to GOs/GOPs ensure RCs and TOPs can issue directives to the GOP, and the GOP follows such directives. They also ensure GOPs render all available emergency assistance as requested. Finally, they require GO/GOPs to coordinate their operations and outages and provide data and information to the BA and TOP. No TOP standard refers to the interaction of a host BA, TOP, or RC with individual BES Elements.

4.11.1 TOP-001-1a — Reliability Responsibilities and Authorities

This standard as it applies to GOPs is reviewed at the requirement level, with only one change recommended.

4.11.1.1 Requirement R3

The purpose of R~~r~~equirement R3 as it relates to GOPs is to ensure the RC and TOP reliability directives are complied with so long as they do not violate safety, equipment, or regulatory or statutory requirements. If a GOP is unable to follow an RC or TOP reliability directive, they are to inform the RC or TOP immediately ~~of such~~. The requirement is applicable to the registered functional entity, not the constituent Elements it operates. *Therefore, there is no need to differentiate applicability to dispersed power producing resources from any other GOP resources, and no change to this requirement is needed.*

4.11.1.2 Requirement R6

The purpose of R~~r~~equirement R6 as it relates to GOPs is to ensure all available emergency assistance to others as requested, unless such actions would violate safety, equipment, or regulatory or statutory requirements. The requirement is applicable to the registered functional entity, not the constituent Elements it operates. *Therefore, there is no need to differentiate applicability to dispersed power producing resources from any other GOP resources, and no change to this requirement is needed.*

4.11.1.3 Requirement R7

The purpose of R~~r~~equirement R7 as it relates to GOPs is to ensure BES facilities are not removed from service without proper notification and coordination with the TOP and, when time does not permit such prior notification and coordination, notification and coordination shall occur as soon as reasonably possible. This is required to avoid burdens on neighboring systems. It should be noted that the purpose of this standard is to keep the TOP informed of all generating Facility capabilities in case of an emergency. It is assumed that required notification and coordination from the GOP to the TOP would be done in real~~-~~time and through verbal communication media. The concern here is how to apply this to a dispersed power producing resource Facility. The SDT recommends that the GOP report at the aggregate Facility level to the TOP any generator outage above 20 MVA for dispersed power producing resource facilities. The justification is based on the following:

- This is consistent with Inclusion I2 of the revised BES definition, which addresses only generating units greater than 20 MVA.
- TOP-002-2.1b Requirement R14 requires real-time notification of changes in Real Power capabilities, planned and unplanned. Setting the threshold at 20 MVA would address routine maintenance on a small portion of the Facility (e.g., 2% of the generators are out of service on any given day) and individual generating units going into a failure. Otherwise, coordinating each individual generating unit outage would burden the TOP without providing an increase in reliability to the interconnected BPS.

Dispersed power producing resource outages should be reported as "x~~X~~ MW out of y~~Y~~ MW are available." *Therefore, the SDT recommends that a modification to the applicability of this requirement is necessary for dispersed power producing resources for generator outages greater than 20 MVA.*

4.11.2 TOP-001-3— Transmission Operations[21]

The purpose of this standard as it relates to GOPs is to ensure TOP directives are complied with so long as they do not violate safety, equipment, or regulatory or statutory requirements. If a GOP is unable to follow a TOP directive, ~~they are~~it is to inform the TOP immediately ~~of such~~. It directs the TOP to issue directives, and as such, the TOP may provide special requirements for dispersed power producing resources for its unique capabilities. *The SDT ~~recommends~~ recommended that Project 2014-3 provide direction for a dispersed power producing resource to be ~~only~~ reported only at the aggregate facility level. ~~If TOP-001-1a R7 is reintroduced, then the recommendation provided above should be included in their efforts.~~*

4.11.3 TOP-002-2.1b — Normal Operations Planning[22]

This TOP standard has five requirements applied to GOPs. Several modifications are recommended below, and the SDT recommends that the most effective and efficient way to accomplish this is through modification of the Applicability s~~S~~ection of this standard.

4.11.3.1 Requirement R3

The purpose of R~~r~~equirement R3 as it relates to GOPs is to ensure a GOP's current ~~-~~day, next-day and seasonal operations are coordinated with its host BAs and TSP. This requirement relates to planned operations at a generator and does not include unplanned operations such as forced or emergency operations. The SDT recommends that this requirement be applied at the aggregate Facility level for dispersed power producing resources. For example, forecasting available ~~MW~~ megawatts at the aggregated Facility level is currently one method used. The SDT does not see any reliability gap ~~in~~ that would prompt this team to apply R3 to any point less than the dispersed power producing resource aggregated Facility level.

The SDT has not found or been made aware of a reliability gap that would prompt this team to apply R3 to any point less than the dispersed power producing resource aggregated Facility level and recommends such modification to the applicability of this requirement.

4.11.3.2 Requirement R13

The purpose of R~~r~~equirement R13 as it relates to GOPs is to ensure Real Power and Reactive Power capabilities are verified as requested by the BA and TOP. The SDT believes a modification to the applicability of this requirement is necessary for dispersed power producing resources. The SDT ~~is recommending~~ recommends that this requirement be applied at the aggregate Facility level for dispersed power producing resources for the following reasons:

- Due to the nature, amount of individual generators at a dispersed power producing resource, internal Real Power losses, and natural inductance and capacitance of dispersed power resource system connected in series, verification of real and reactive capabilities should be conducted at the dispersed power producing resource aggregate Facility level. Performing verification in this manner will provide an actual net real and reactive capability, which would be seen by both the

[21] Note that TOP-001-2 was adopted by the Board and remanded by FERC. TOP-001-2 is currently under revision as part of Project 2014-03 – Revisions to TOP and IRO Standards, and was posted for additional ballot period that is scheduled to close January 7, 2015 as TOP-001-3.

[22] The GOP applicability is removed in TOP-002-3, which was adopted by the Board. However, TOP-002-3 was included in the proposed remand by FERC and is subject to revision as part of Project 2014-3 – Revisions to TOP and IRO s~~S~~tandards.

BA and TOP. In addition, performing verification in this manner is also consistent with operating agreements such as an interconnection agreement, which the dispersed power resource has with the TOP and BA.

- MOD-025-2 also provides that verification for any generator ~~<20MVA~~ less than 20MVA may be completed on an individual unit basis or as a "group." Reporting capability at the aggregated Facility level is consistent with the MOD-025-2 provision for group verification.

The SDT recommends a modification to the applicability of this requirement at the aggregated Facility level for dispersed power producing resources.

4.11.3.3 Requirement R14

The purpose of R~~r~~equirement R14 as it relates to GOPs is to ensure BAs and TOPs are notified of changes in real output capabilities without any intentional time delay. It should be noted that the purpose of this requirement is to address unplanned changes in real output capabilities. It is assumed the required notification and coordination from the GOP to the BA and TOP would be done in real ~~-~~time and through verbal communication media. The concern here is how to apply this to dispersed power producing resources. The SDT recommends that the GOP notify at the aggregate Facility level to the TOP any unplanned changes in real output capabilities above 20 MVA. The justification is based on the following:

- This is consistent with Inclusion I2 of the revised BES definition, which includes generating units greater than 20 MVA; and
- TOP-002-2.1b R14 requires real-time notification of changes in Real Power capabilities, planned and unplanned. Setting the threshold at 20 MVA would address routine maintenance on a small portion of the Facility (e.g. 2% of the generators are out of service on any given day) and individual generating units going into a failure. Otherwise, coordinating each individual generating unit outage would burden the TOP without providing an increase in reliability to the interconnected BPS.

Changes in the real output capabilities of d~~D~~ispersed generation resources ~~changes in real output capabilities~~ should be reported as ~~X~~ "x MW out of y~~Y~~ MW are available." *The SDT recommends that a modification to the applicability of this requirement is necessary for dispersed power producing resources for unplanned outages greater than 20 MVA.*

4.11.3.4 Requirement R15

The purpose of ~~requirement~~ Requirement R15 as it relates to GOPs is to ensure BAs and TOPs are provided a forecast (e.g., seven days) of expected Real Power. The SDT believes this requirement as requested by the BA or TOP is being applied at the aggregate Facility level for dispersed power producing resources.

Based on the SDT's experience, expected Real Power forecasts (e.g. ~~5~~ five or seven-day~~7~~ forecast) for a dispersed power producing resource traditionally have been~~has been traditionally~~ coordinated with the BA and TOP at the aggregate Facility level for dispersed power producing resources. *Therefore, the SDT recommends that R15 be applied at the aggregate Facility level for dispersed power resources and, as such, modification to the applicability~~applicability~~ of this requirement is necessary.*

4.11.3.5 Requirement R18

The purpose of ~~requirement~~ Requirement R18 as it relates to a GOP is to ensure uniform line identifiers are used when referring to transmission facilities of an interconnected network. The standard applies to

transmission

facilities of an interconnected network, which would not apply to any Elements within the dispersed generation Facility. There is no need to differentiate applicability to dispersed generation resources from any other GOP resources. *Therefore, the applicability of this requirement does not need to be changed for dispersed generation resources.*

4.11.4 TOP-003-1— Planned Outage Coordination

This TOP Standard has three requirements applied to GOPs. Modification to one of these requirements is recommended.

4.11.4.1 Requirement R1

The purpose of ~~requirement~~ Requirement R1 as it relates to GOPs is to ensure TOPs are provided planned outage information on a daily basis for any scheduled generator outage greater than~~>~~ 50 MW for the next day. *Therefore, the applicability of this requirement does not need to be changed for dispersed generation resources.*

4.11.4.2 Requirement R2

The purpose of ~~requirement~~ Requirement R2 as it relates to GOPs is to ensure all scheduled outages of voltage~~-~~ regulating equipment ~~scheduled outages~~ are planned and coordinated with affected BAs and TOPs. A modification to the applicability of this requirement is necessary for dispersed power producing resources. The SDT recommends that this requirement be applied at the aggregate Facility level for dispersed power producing resources.

Based on the SDT's experience, scheduled outages of voltage~~-~~ regulating equipment at a dispersed power producing resource traditionally has been ~~traditionally~~ provided to the BA and TOP at the aggregate Facility level for dispersed power producing resources. Outages of voltage~~-~~ regulating equipment at a dispersed power producing resource are coordinated typically as a reduction in Reactive Power capabilities, specifying whether it is inductive, capacitive, or both. Additionally, automatic voltage regulators that do not necessarily provide Reactive Power, but direct the actions of equipment that do supply Reactive Power, are typically coordinated at the aggregate Facility level as they usually are the master controller for all voltage~~-~~ regulating equipment at the Facility. A key aspect of the SDT project is to maintain the status quo, if it is determined not to cause a reliability gap. *The SDT has not found or been made aware of a reliability gap, ~~which~~ that would prompt this team to apply R2 to any point less than the dispersed power producing resource aggregated Facility level and, as such, determined a modification to the applicability of this requirement is necessary for dispersed power producing resources.*

4.11.4.3 Requirement R3

The purpose of ~~requirement~~ Requirement R3 as it relates to GOPs is to ensure scheduled outages of telemetering and control equipment and associated communication channels are planned and coordinated among BAs and TOPs. Based on the SDT's technical expertise, scheduled outages of telemetering and control equipment and associated communication channels at a dispersed power producing resource traditionally have been ~~traditionally~~ provided to the BA and TOP at the aggregate Facility level ~~for dispersed power producing resources~~. In addition, only scheduled outages of telemetering and control equipment and associated communication channels that can affect the BA and TOP are coordinated with the BA and TOP. *Therefore, the applicability of this requirement does not need to be changed for dispersed power producing resources.*

4.11.5 TOP-006 — Monitoring System Conditions

The purpose of this standard as it relates to GOPs is to ensure BAs and TOPs know the status of all generation resources available for use as informed by the GOP. It should also be noted that the purpose of this standard is to ensure that critical reliability parameters are monitored in real -time. It then can be extrapolated that the requirement, "GOP shall inform…," is done by sending dispersed power producing resource telemetry in real -time and through a digital communication medium, such as an ICCP link or RTU. The SDT ~~feels~~ concludes that a modification to the applicability of this requirement is necessary for dispersed power producing resources. The SDT is recommending that this requirement be applied at the aggregate Facility level for dispersed power producing resources for the following reasons:

- This is consistent with Inclusion I2 of the revised BES definition, which includes generating units greater than 20 MVA. If removing less than ~~<~~20 MVA would cause a burden to the BPS, then the threshold for inclusion in the BES would have been less than 20 MVA.~~;~~
- Routine maintenance is frequently completed on a small portion of the entire Facility (e.g. 2% of the generators are out of service on any given day) such as to not have a significant impact to the output capability of the Facility. Additionally, it is not uncommon to have individual generating units at a dispersed power producing resource to go into a failure mode due to internal factors of the equipment, such as hydraulic fluid pressure tolerances, gearbox -bearing thermal tolerances, etc. As such, coordinating each individual generating unit outage would burden the TOP without providing an increase in reliability to the interconnected BPS~~; and~~.
- As this standard requires real-time monitoring, this is most likely completed through a digital medium such as an ICCP link or RTU. The data that a dispersed power resource provides to the BA and TOP in real -time should include the aggregate active power output of the Facility, among other telemetry points. These data specifications are usually outlined in interconnection agreements among the parties.

Based on the SDT's technical expertise, BAs and TOPs are informed by the GOP of all generation resources available at the dispersed power producing resource at the aggregate Facility level. Traditionally the dispersed power producing resources ~~are~~ provid~~e~~ing the BA and TOP, at minimum, the following telemetry points in real -time: aggregate Real Power, aggregate Reactive Power and main high-side circuit breaker status. A key aspect of the SDT project is to maintain the status quo, if it is determined not to cause a reliability gap. *The SDT has not found or been made aware of a reliability gap, ~~which~~ that would prompt this team to apply these requirement to any point less than where the dispersed power producing resource aggregates and, as ~~in~~ such, recommends a modification to the applicability of this requirement ~~is necessary~~ for dispersed power producing resources.*

4.12 TPL

At the time of this paper, these standards do not affect GOs or GOPs directly. Input from GO or GOP entities is provided to transmission planning entities through the MOD standards. *Therefore, the applicability of the TPL standards does not need to be changed for dispersed power producing resources.*

4.13 VAR

The VAR standards exist to ensure that voltage levels, reactive flows, and reactive resources are monitored, controlled, and maintained. T~~here are t~~wo VAR S~~s~~tandards ~~that~~ apply to GOs and/or GOPs.

The voltage and/or reactive schedule provided by TOPs is specified to be at the point of interconnection or the point specified in the interconnection agreement.

4.13.1 VAR-001 — Voltage and Reactive Control (WECC Regional Variance)

The purpose of this standard as it relates to GOPs in WECC is to ensure a generator voltage schedule is issued that is appropriate for the type of generator(s) at a specific Facility. Additionally, it requires GOPs to have a methodology for how the voltage schedule is met, taking into account the type of equipment used to maintain the voltage schedule. Based on the SDT's technical expertise, voltage control and voltage schedule adherence for dispersed power producing resources occurs at the aggregate Facility level. There is no need to differentiate dispersed generation resources from any other GOP resources. *Therefore, the applicability of VAR-001 does not need to be changed for dispersed generation resources.*

4.13.2 VAR-002-2b — Generator Operation for Maintaining Network Voltage Schedules
VAR-002-3 — Generator Operation for Maintaining Network Voltage Schedules

The purpose of these standards as they relate to GOs and GOPs is to ensure generators operate in automatic voltage control mode as required by the TOP voltage or reactive power schedule provided to ensure voltage levels, reactive flows, and reactive resources are maintained within applicable Facility Ratings to protect equipment and reliability of the Interconnection. Based on the SDT's technical expertise, voltage control and voltage schedule adherence for dispersed power producing resources occurs at the aggregate Facility level, and such guidance should be provided.

In addition, the voltage-controlling equipment and the methodology to ensure the Facility has an automatic and dynamic response to ensure the TOP's instructions are maintained can be very different for each Facility. It is implied in VAR-001-3 that each TOP should understand capabilities of the generation Facility and the requirements of the transmission system to ensure that a mutually agreeable solution/schedule is used.

4.13.3 VAR-002-2b — Requirement R3.1
VAR-002-3 — Requirement R4

4.13.4 The purpose of these requirements is to ensure that a GOP notifies the TOP, within 30 minutes, of any status and capability changes of any generator Reactive Power resource, including automatic voltage regulator, power system stabilizer, or alternative voltage controlling device. Based on the experience of the SDT, status and capability changes ~~is~~ are traditionally coordinated at the aggregate Facility level point of interconnection. *Therefore, the SDT has recommended changes to the standard to clarify the applicability of VAR-002-2b R3.1 and VAR-002-3 R4 for dispersed power producing resources. These changes were successfully balloted in VAR-002-4 on November 6, 2014, and approved by the Board on November 13, 2014.* ~~**VAR-002-2b — Requirement R4**~~
~~**VAR-002-3 — Requirement R5**~~

4.13.4 VAR-002-2b — Requirement R4
VAR-002-3 — Requirement R5

The purpose of these requirements is to ensure that Transmission Operators and Transmission Planners have appropriate information and provide guidance to the GOP in regard~~s~~ to Generator Operator's ~~s~~ transformers to ensure voltage levels, reactive flows, and reactive resources are maintained within

applicable Facility Ratings to protect equipment and reliability of the Interconnection. Based on the experience of the SDT, dispersed power producing resources' individual generator transformers traditionally have ~~traditionally~~ been excluded from the requirements of VAR-002-2b R4 and VAR-002-3 R5, as they are not used to improve voltage performance on the Interconnection. As such, applicability should be limited to transformers with at least one winding at a voltage of 100 kV or above. *Therefore, the SDT has recommended changes to the standard to clarify the applicability of VAR-002-2b R4 and VAR-002-3 R5 for dispersed generation resources. These changes were successfully balloted in VAR-002-4 on November 6, 2014, and approved by the Board on November 13, 2014.*

4.14 CIP

4.14.1 CIP ~~v~~Version 5

The CIP standards are still under revision in Project 2014-02. The DGR SDT and the CIP SDT continue to coordinate revisions to the CIP standards, and will update this section to reflect the outcome of that effort at the appropriate time.

The CIP standards ensure physical and cyber security for BES Cyber Assets and BES Cyber Systems critical to the reliability and security of the BES. CIP-002 identifies critical assets or systems of a Facility, while CIP-003 to CIP-011 depend on the outcome of the CIP-002 assessment to determine applicability.

During the first comment period for the Project 2014-02 CIP Version 5 Revisions, the SDT ~~first comment period, it~~ received comments to modify CIP-003-6 in the Applicability ~~Section~~section. The CIP SDT made ~~drastic~~ significant modifications to the second posting of CIP-003-6 to take into account~~s~~ all of the comments received., ~~which~~ Thiswas posted for an additional 45-day comment and ballot period on September 3, 2014.

At its September meeting, the DGR SDT had a focused discussion with the CIP SDT surrounding the technical nature of the dispersed power producing resources and how it relates to the CIP standards. The coordinating effort resulted in discussions of the revised CIP-003-6. As for that posted revised standard, the CIP SDT took the approach of including an Attachment 1 for Responsible Entities. ~~The~~ Attachment 1 requires elements to be developed in Responsible Entities' cyber-security plan~~(s)~~ for assets containing low- impact BES ~~Cyber~~ cyber ~~Systems~~systems. The elements in CIP-003-6, Attachment 1 allow flexibility for the controls ~~–~~to be established for each of the main four elements below. The CIP SDT encourages observers of the DGR SDT to review ~~the~~ Attachment 1 in detail. ~~Here~~ Below is some information regarding the attachment.

Element 1: Security Awareness

The intent of the security awareness program is for entities to reinforce good cyber-security practices with their personnel at least once every 15 calendar months. ~~It is up to t~~The entity ~~as to~~decides the topics and how it schedules the~~mse topics~~. The Responsible Entity should be able to produce the awareness material that was delivered and the delivery method(s) (posters, emails, topics at staff meetings, etc.) that were used. The SDT does not intend that the Responsible Entity must maintain lists of recipients and track the reception of the awareness material by personnel.

Element 2: Physical Security

The Responsible Entity has flexibility in the controls used to restrict physical access to low- impact BES Cyber Systems at a BES asset using one or a combination of access controls, monitoring controls, or other operational, procedural, or technical physical security controls. Entities may utilize perimeter controls (e.g., fences with locked gates, guards, site access policies, etc.) and/or more granular areas of physical access control in areas where low- impact BES Cyber Systems are located, such as control rooms or control houses. User authorization programs and lists of authorized users are not required.

Element 3: Electronic Access Controls

Where Low Impact External Routable Connectivity (LERC) or Dial-up Connectivity exists, the Responsible Entity must document and implement controls that include the LERC and Dial-up Connectivity to the BES asset such that the low- impact BES Cyber Systems located at the BES asset are protected. Two glossary terms are included in order to help clarify and simplify the language in Attachment 1. The SDT's intent in creating these terms is to avoid confusion with the similar concepts and requirements (ESP, EAP, ERC, EACMS) needed for high- and medium- impact BES Cyber Systems by ~~utilizing~~ using separate terms that apply only to assets containing low- impact BES Cyber Systems.

Element 4: Cyber Security Incident Response

The entity should have one or more documented cyber security incident response plan~~s~~ that includes each of the topics listed. For assets that do not have LERC, it is not the intent to increase their risk by increasing the level of connectivity in order to have real-time monitoring. The intent is, if in the normal course of business suspicious activities are noted at an asset containing low- impact BES Cyber Systems, ~~there is~~ a cyber security incident response plan ~~that~~ will guide the entity through responding to the incident and reporting the incident if it rises to the level of a Reportable Cyber Security Incident.

Therefore, the DGR SDT recommends that no changes be made to the proposed CIP-003-6. CIP-002-5.1 needs to remain as is, because entities must go through the process for identifying and categorizing ~~its~~ their BES Cyber Systems and ~~their~~ associated BES Cyber Assets. The controls put in place for proposed CIP- 003-6, Attachment 1, are not burdensome, are realistic and achievable, and do~~es~~ not express undue compliance burden. In conclusion, the DGR SDT states that the reliability objective of these controls is~~are~~ adequate and the applicability of CIP-003-6 should not be modified.

The SDT states that the CIP Version 5 Revisions SDT should consider developing guidance documentation around the following areas:

- Low ~~I~~impact BES Cyber Systems that must comply with a limited number of requirements, all located in CIP-003-5. The only technical requirement is R2, which will be modified during the current drafting activity to add clarity to the requirement. The SDT notes that the CIP Version 5 Revisions SDT should consider developing guidance around how this requirement relates to dispersed generation;
- Any programmable logic device that has the capability to shut down the plant within 15 minutes~~; and~~
- Remote access from third- party entities into the SCADA systems that control the aggregate capacity of a Facility should be assessed to determine if there is a need of any additional cyber security policies.

The SDT intends to recommend guidance for those companies that only operate their turbines from one central location. Individual Elements lumped into a BES Cyber System should be addressed. When operations are on a turbine-by-turbine basis, the SDT believes there should not be rigid controls in place. The inability to "swim upstream" should be addressed as well. Further, the guidance intends to address when manufacturers operate or have control of the SCADA environment to conduct troubleshooting and other tasks, and ensure that proper security is in place.

NERC staff has committed to facilitate communication between the SDT and the CIP Version 5 Revisions SDT as appropriate to ensure alignment and to develop language for guidance, coordinated between the two SDTs. *Therefore, the applicability of CIP standards does not need to be changed for dispersed generation resources.*

APPENDIX A: LIST OF STANDARDS 37

APPENDIX B: LIST OF STANDARDS RECOMMENDED FOR FURTHER REVIEW 38

1 Executive Summary

The purpose of this White Paper is to provide background and technical rationale for proposed revisions to the applicability of several North American Electric Reliability Corporation (NERC) Reliability Standards, and in some cases the standard requirements. The goal of the NERC Project 2014-01 Standards Applicability for Dispersed Generation Resources[1] standard drafting team (SDT) is to ensure that the Generator Owners (GOs) and Generator Operators (GOPs) of dispersed power producing resources are appropriately assigned responsibility for requirements that impact the reliability of the Bulk Power System (BPS), as the characteristics of operating dispersed power producing resources can be unique. In light of the revised Bulk Electric System (BES) definition approved by the Federal Energy Regulatory Authority (FERC) in 2014,[2] the intent of this effort is generally to maintain the status quo for applicability of the standards as they have been applied over time with respect to dispersed power producing resources where the status quo does not create a reliability gap.

The SDT reviewed all standards that apply to GOs and GOPs[3] and determined how each standard requirement should be appropriately applied to dispersed power producing resources, categorized as follows:

- The existing standard language was appropriate when applied to dispersed power producing resources and does not need to be addressed;
- The existing standard language was appropriate when applied to dispersed power producing resources, but additional NERC guidance documentation is needed to clarify how to implement the requirements for dispersed power producing resources; and
- The existing standard language needs to be modified in order to account for the unique characteristics of dispersed power producing resources. This could be accomplished through the applicability section of the standard in most cases or, if required, through narrowly tailored changes to the individual requirements.

From this review, the SDT determined that three (3) Reliability Standards required immediate attention to clarify the applicability of the Reliability Standards to dispersed power producing resources for the benefit of industry stakeholders. These standards (relevant versions) are:

- PRC-004;[4]
- PRC-005;[5] and
- VAR-002.

The SDT recognized that many other standards[6] required further review to determine the necessity and the type of clarification or guidance for the applicability to dispersed power producing resources. This

[1] Although the BES definition uses the term "dispersed power producing resources," the SAR and the SDT also use the term "dispersed generation resources." For the purposes of this paper, these terms are interchangeable.
[2] Glossary of Terms Used in NERC Reliability Standards, updated March 12, 2014.
[3] See Appendix A.
[4] Reliability Standard PRC-004 was revised as part of Project 2010-05.1 Protection Systems: Misoperations.
[5] Reliability Standard PRC-005 was revised as part of Project 2007-17.3 Protection System Maintenance and Testing – Phase 3.
[6] See Appendix B.

necessity is based on how each standard requirement, as written, would apply to dispersedpower producing resources and the individual generating units at these facilities, considering the now currently effective BES definition. The proposed resolutions target the applicability of the standard or target specific individual requirements. There are additional methods to ensure consistent applicability throughout the Regions, including having guidance issued by NERC through Reliability Standard Audit Worksheet (RSAW) language revisions. These tools, among others, have been considered and employed by the SDT throughout the drafting effort.

This White Paper includes: (1) a description of the history of standards applicability to dispersed power producing resources; (2) identification of circumstances and practices that are unique to dispersed power producing resources; and (3) a determination of the priority to address standards, supported by corresponding technical justification.

The SDT's intent is to modify this document over the course of this project to document the SDT's rationale and technical justification for each standard until the work of the SDT is complete. The SDT considers the sections of the White Paper that address the high-priority standards to be in final draft form. The SDT may provide further revisions to the remainder of the White Paper.

2 Purpose

The purpose of this White Paper is to provide background and technical rationale for proposed revisions to the applicability of several Reliability Standards[7] or requirements that apply to GOs and/or GOPs. The goal of the proposed applicability changes is to provide the GOs and GOPs of dispersed generation resources with clarity regarding their responsibility for requirements that impact the reliability of the BPS, as the characteristics of operating dispersed generation can be unique. The SDT seeks to provide clarity through the method most appropriate for each standard, such as by: (1) revising applicability language in the standard; (2) revising language in the requirements to address changes to applicability; (3) recommending changes to the RSAW associated with the standard; or (4) recommending a reliability guideline or reference document.

This document describes the design, operational characteristics, and unique features of dispersed power producing resources. The recommendations identified in this document consider the purpose and time horizon of the standards and requirements, as well as the avoidance of applying requirements in a manner that has no significant effect on reliability.[8] This document provides justification of, and proposes revisions to, the applicability of the Reliability Standards and requirements, both existing and in development, and should be considered guidance for future standard development efforts. However, please note that the recommendations provided in this paper are subject to further review and revision.

Note that while this White Paper may provide examples of dispersed power producing resources, the concepts presented are not specific to any one technology. The SDT in general has referenced the *BES Definition Reference Document*[9], which also refers to "dispersed power producing resources." Although the BES definition uses the term "dispersed power producing resources," the Standard Authorization Request (SAR) and the SDT also use the term "dispersed generation resources." For the purposes of this paper, these terms are interchangeable.

[7] Note that "Reliability Standard" is defined in the NERC Glossary as "approved by FERC," but that the SDT reviewed approved standards, as well as revisions to standards proposed in other projects.

3 Background

Industry stakeholders submitted a SAR to the NERC Standards Committee, requesting that the applicability of Reliability Standards or the requirements of Reliability Standards be revised to ensure that the Reliability Standards are not imposing requirements on dispersed generation resource components that are unnecessary or counterproductive to the reliability of the BPS. The SDT's focus has been to ensure that Reliability Standards are applied to dispersed power producing resources to support an effective defense-in-depth strategy and an adequate level of reliability for the interconnected BPS.

For purposes of this effort, dispersed power producing resources are those individual resources that aggregate to a total capacity greater than 75 MVA gross nameplate rating, and that are connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage of 100 kV or above. This request is related to the approved definition of the BES from Project 2010-17,[10] which resulted in the inclusion of distinct components of dispersed generation resources.

3.1 BES Definition

The BES definition[11] includes the following inclusion criterion addressing dispersed generation resources:

> *I4. Dispersed power producing resources that aggregate to a total capacity greater than 75 MVA (gross nameplate rating), and that are connected through a system designed primarily for delivering such capacity to a common point of connection at a voltage of 100 kV or above. Thus, the facilities designated as BES are:*
>
> *a) the individual resources; and*
> *b) the system designed primarily for delivering capacity from the point where those resources aggregate to greater than 75 MVA to a common point of connection at a voltage of 100 kV or above.*

The *BES Definition Reference Document*[12] includes a description of what constitutes a dispersed generation resource:

> *Dispersed power producing resources are small-scale power generation technologies using a system designed primarily for aggregating capacity providing an alternative to, or an enhancement of, the traditional electric power system. Examples could include but are not limited to: solar, geothermal, energy storage, flywheels, wind, micro-turbines, and fuel cells.*

3.2 Dispersed Power Producing Resources

Dispersed power producing resources are often considered to be variable energy resources such as wind and solar. This description is not explicitly stated in the BES definition; however, NERC and FERC characterize variable generation in this manner regarding the purpose of Inclusion I4 of the definition.[13] Therefore, the SDT is considering the reliability impacts of variable generation that depends on a primary fuel source that varies over time and cannot be stored.[14] Reliably integrating high levels of variable resources—wind, solar, ocean, and some forms of hydro—into the BPS require significant changes to traditional methods used for system planning and operation.[15] While these resources provide challenges to system operation, they are instrumental in meeting government-established renewable portfolio standards and requirements that are based on vital public interests.[16]

3.2.1 Design Characteristics

For dispersed power producing resources to be economically viable, it is necessary for the equipment to be geographically dispersed. The generating capacity of individual generating modules can be as small as a few hundred watts to as large as several megawatts. Factors leading to this dispersion requirement include:

- Practical maximum size for wind generators to be transported and installed at a height above ground to optimally utilize the available wind resource;
- Spacing of wind generators geographically to avoid interference between units;
- Solar panel conversion efficiency and solar resource concentration to obtain usable output; and
- Cost-effective transformation and transmission of electricity.

The utilization of small generating units results in a large number of units (e.g., several hundred wind generators or several million solar panels) installed collectively as a single facility that is connected to the Transmission system.

Dispersed power producing resources interconnected to the transmission system typically have a control system at the group level that controls voltage and power output of the Facility. The control system is capable of recognizing the capability of each individual unit or inverter to appropriately distribute the contribution required of the Facility across the available units or inverters. The variable generation control system must also recognize and account for the variation of uncontrollable factors such as wind speed and solar irradiance levels. Thus, for some standards discussed in this paper, it is appropriate to apply requirements at the plant level rather than the individual generating unit.

3.2.2 Operational Characteristics

Dispersed power producing resources often rely on a variable energy source (wind, for example) that is not able to be stored. Because of this, a Facility operator cannot provide a precise forecast of the expected output to a Balancing Authority (BA), Transmission Operator (TOP) or Reliability Coordinator (RC); however, short-term forecasting capability is improving and thus reducing uncertainty.[17] The forecasting and variable operating conditions are well understood by BAs, TOPs, and RCs as evidenced by the successful operation of these generating resources over the years. Dispersed generation resources by their nature result in each individual generating unit potentially experiencing varied power system parameters (e.g., voltage, frequency, etc.) due to varied impedances and other variations in the aggregating facilities' design.

Many older dispersed power producing resources are limited in their ability to provide essential reliability services. However, due to technological improvements, newer dispersed generation resources are capable of providing system support for voltage and frequency. For efficiency, the facilities are designed to provide the system requirements at the point of interconnection to the transmission system.

3.2.3 Reliability Impact

A dispersed power producing resource is typically made up of many individual generating units. In most cases, the individual generating units are similar in design and from one manufacturer. The aggregated capability of the Facility may in some cases contribute significantly to the reliability of the BPS. As such, there can be reliability benefits from ensuring the equipment utilized to aggregate the individual units to a common point of connection are operated and maintained as required in certain applicable NERC standards. When evaluated individually, however, the individual generating units often do not provide a significant impact to BPS reliability, as the unavailability or failure of any one individual generating resource may have a negligible impact on the aggregated capability of the Facility. The SDT acknowledges that FERC addressed the question of whether individual resources should be included in the BES definition in Order Nos. 773 and 773-A and concluded that individual wind turbine generators should be included as part of the BES. The SDT is not challenging this conclusion, but rather is addressing the applicability of standards on a requirement-by-requirement basis as necessary to account for the unique characteristics of dispersed generation. Thus, the applicability of requirements to individual generating units may be unnecessary except in cases where a common-mode issue exists that could lead to a loss of a significant number of units or the entire Facility in response to a transmission system event.

3.3 Drafting Team Efforts

The SDT approached this project in multiple phases. First, after a thorough discussion of the new definition of the BES, the SDT reviewed each standard, as shown in Appendix A, at a high level to recommend changes that would promote consistent applicability for dispersed power producing resources through the entire set of Reliability Standards. This review provided the type of changes proposed, the justification for the changes, and the priority of the changes. The SDT documented its review in this White Paper, which will continue to be updated throughout the SDT efforts. The second phase, currently

[17] "*Electricity Markets and Variable Generation Integration,*" WECC, January 6, 2011. https://www.wecc.biz/committees/StandingCommittees/JGC/VGS/MWG/ActivityM1/WECC%20Whitepaper%20-%20Electricity%20Markets%20and%20Variable%20Generation%20Integration.pdf

in progress, includes revising standards where necessary and supporting the balloting and commenting process.

3.3.1 Scope of Standards Reviewed

Initially, the focus of the standards review was on standards and requirements applicable to GOs and GOPs. However, during discussions, a question was raised to the SDT regarding whether consideration is necessary for other requirements that affect the interaction of a Balancing Authority (BA), Transmission Operator (TOP), or Reliability Coordinator (RC) with individual BES Elements. For example, a requirement that states, "an RC shall monitor BES Elements" may unintentionally affect the RC operator due to the revised BES definition. As such, the SDT took a high-level look at all standards adopted by the NERC Board of Trustees (Board) or approved by FERC to ensure this issue was not significant.

All standards that were reviewed are listed in Appendix A along with the status of the standards as of December 11, 2014. The fields in Appendix A include the following:

- List of standards (grouped by approval status)
- Approval status of the standards (status types listed below):
  - Subject to Enforcement
  - Subject to Future Enforcement
  - Filed and Pending Regulatory Approval
  - Pending Regulatory Filing
  - Designated for Retirement (two standards—MOD-024-1 and MOD-025-1—officially listed as Filed and Pending Regulatory Approval but will be superseded by MOD-025-2)
  - In Concurrent Active Development
- Indication of change or additional review necessary

The SDT also reviewed, at a high level, any approved regional standards. In cases where a change is recommended to a regional standard, the SDT will notify the affected Region. In addition, the SDT is prepared to provide recommendations to other active NERC standard development efforts, where appropriate.

Status	Number of Standards	Number of Standards to be Addressed (Standard, RSAW, Guidance or Further Review)
NERC Standards	**166**	**27**
Subject to Enforcement	101	12
Subject to Future Enforcement	20	5
Pending Regulatory Approval	28	4
Pending Regulatory Filing	7	0
Designated for Retirement	2	0
Proposed for Remand	8	6
Region-specific Standards (*Out of Scope)	**17**	**4**
Subject to Enforcement	15	3
Subject to Future Enforcement	2	1
Pending Regulatory Approval	0	0
Grand Total	**183**	**31**

3.3.2 Reliability Objectives

The SDT used the following reliability objectives to review the standards:

- Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC standards;
- The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand;
- Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably;
- Plans for Emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained, and implemented;
- Facilities for communication, monitoring, and control shall be provided, used, and maintained for the reliability of interconnected bulk power systems;
- Personnel responsible for planning and operating interconnected bulk power systems shall be trained and qualified and have the responsibility and authority to implement actions;
- The reliability of the interconnected bulk power systems shall be assessed, monitored, and maintained on a wide-area basis; and
- Bulk power systems shall be protected from malicious physical or cyber attacks.

3.3.3 Prioritization Methodology

The SDT established a prioritization to review and modify applicability changes recommended to NERC standards and requirements. The SDT evaluated each requirement to identify the appropriate applicability to support reliability of the BPS. In general, any standard or requirement the SDT determined to require modification was assigned a high, medium, or low priority. The standards and requirements priorities were established as follows:

- High priority was assigned so that standard or requirement changes would be made quickly enough to avoid an entity having to expend inordinate resources prematurely to comply with a standard or requirement that, after appropriate modification, would not be applicable to that entity.
- Medium priority was assigned if significant effort and resources with no appreciable reliability benefit would be required by an entity to be compliant.
- Low priority was assigned to other changes that may need to be made to further ensure requirements add to reliability, but are not perceived as a significant compliance burden.

The prioritization of each recommendation is identified in Appendix B.

- List of standards (grouped by priority);
- Approval status of the standards (same designations as used in Appendix A);
- Recommendation of changing the Applicability section of the standard or by changing the applicability for specific requirements; and
- Recommendation of which applicability options should apply.

4 Technical Discussion

This section provides a review of each group of standards, focusing on the impact of the BES definition on reliability and compliance efforts. This discussion proposes a resolution for each standard, whether it is a change in the Applicability section or in a specific requirement, clarification in a guidance document, or no action needed.

4.1 BAL

The group of BAL standards focuses primarily on ensuring the Balancing Authority (BA) has the awareness, ability, and authority to maintain the frequency and operating conditions within its Balancing Authority Area. Only two standards in this group affect GO and/or GOP, and no BAL standard reviewed affected the interaction of a host BA, TOP, or RC with individual BES Elements.

4.1.1 BAL-005 — Automatic Generation Control

The purpose of this standard, as it applies to GOPs, is to ensure that all facilities electrically synchronized to the Interconnection are included within the metered boundary of a Balancing Authority Area so that balancing of resources and demand can be achieved. Ensuring the Facility as a whole is within a Balancing Authority Area ensures the individual units are included. *Therefore, the applicability of the BAL-005 standard does not need to be changed for dispersed power producing resources.*

4.1.2 BAL-001-TRE-1 — Primary Frequency Response in the ERCOT Region

The purpose of BAL-001-TRE-1 is to maintain Interconnection steady-state frequency within defined limits. This standard should be modified to clarify the applicability for dispersed power producing resources to the total plant level to ensure coordinated performance. However, this is a regional standard and not part of the SDT scope. *The SDT will communicate this recommendation to the relevant Region.*

4.2 COM

The COM standards focus on communication between the RC, BAs, TOPs, and GOPs. The only requirements in any of the current or future enforceable standards that apply to the GOP are clearly intended to apply to the individual GOP registered functional entity (i.e., requires communication between GOPs, TOPs, BAs, and RCs), not the constituent Elements it operates. Consequently, there is no need to differentiate the GOP's obligation for dispersed power producing resources from any other resources. *Therefore, the applicability of the COM-001-2, COM-002-2a, and COM-002-4 standards that were reviewed does not need to be changed for dispersed power producing resources.*

4.3 EOP

The EOP standards focus on emergency operations and reporting. The standards that apply to GO and/or GOP entities are EOP-004 and EOP-005. No EOP standard reviewed affects the interaction of a host BA, TOP, or RC with individual BES Elements.

4.3.1 EOP-004 — Event Reporting

The purpose of this standard is to improve the reliability of the BES by requiring the reporting of events by responsible entities. The requirements of this standard that apply to the GO and GOP appear to apply

to the individual GO and GOP registered functional entity, not the constituent elements. *The SDT has considered whether there is a need to differentiate dispersed power producing resources from any other GO and/or GOP resource and determined that no changes are required to the standard.*

4.3.2 EOP-005 — System Restoration from Blackstart Resources

EOP-005 ensures plans are in place to restore the grid from a de-energized state. The requirements that apply to a GOP are primarily for individual generation facilities designated as Blackstart Resources, with one requirement to participate in restoration exercises or simulations as requested by the RC. The inclusion of Blackstart Resources is already identified in the BES definition through Inclusion I3. The expectation is that all registered GOPs will participate in restoration exercises as requested by their RC. *Therefore, the applicability of EOP-005 does not need to be changed for dispersed power producing resources.*

4.4 FAC

The FAC standards focus on establishing ratings and limits of the Facility and interconnection requirements to the BES. Several standards apply to GOs and/or GOPs. No FAC standard reviewed affects the interaction of a host BA, TOP, or RC with individual BES Elements.

4.4.1 FAC-001 — Facility Connection Requirements

Requirements R2 and R3 of this standard apply to any GO that has an external party applying for interconnection to the GO's existing Facility in order to connect to the transmission system. This scenario is uncommon and there is no precedent for applicability of this standard to dispersed power producing resources known to the SDT. Current practice primarily includes the GO stating that they will comply with the standard if this scenario is ever realized. This standard allows the GO to specify the conditions that must be met for the interconnection of the third party, thus providing inherent flexibility to tailor the requirements specifically for the unique needs of the Facility. *Therefore, the applicability of FAC-001 does not need to be changed for dispersed power producing resources.*

4.4.2 FAC-002 — Coordination of Plans for New Facilities

The purpose of FAC-002 is to ensure coordinated assessments of new facilities. The requirement applicable to GOs requires coordination and cooperation on assessments to demonstrate the impact of new facilities on the interconnected system and to demonstrate compliance with NERC standards and other applicable requirements. The methods used to demonstrate compliance are independent of the type of generation and are typically completed at the point of interconnection. *Therefore, the applicability of FAC-002 does not need to be changed for dispersed power producing resources.*

4.4.3 FAC-003 — Transmission Vegetation Management

The purpose of this standard is to ensure programs and efforts are in place to prevent vegetation-related outages. This standard applies equally to dispersed generation facilities and traditional Facilities in both applicability and current practices, as it pertains to overhead transmission lines of applicable generation interconnection Facilities. *Therefore, the applicability of FAC-003 does not need to be changed for dispersed power producing resources.*

4.4.4 FAC-008 — Facility Ratings

FAC-008 ensures Facility ratings used in the planning and operation of the BES are established and communicated. The Facility ratings requirement has historically been applicable to dispersed power producing resources, and current practices associated with compliance are similar to traditional generation facilities. There is inherent flexibility in the standard requirements for the GO to determine the methodology utilized in determining the Facility ratings.

To identify the Facility rating of a dispersed power producing resource, the analysis of the entire suite of Facility components is necessary to adequately identify the minimum and maximum Facility Rating and System Operating Limits, and thus there would be no differentiation between the compliance obligations between dispersed power producing resources and traditional generation. *The SDT believes the industry and Regions would benefit from additional guidance on FAC-008 in the form of the technical guidance provided below.*

Guidelines and Technical Basis

FAC-008 ensures facility ratings used in the planning and operation of the BES are established and communicated. The facility ratings requirement has historically been applicable to dispersed power producing resources, and current practices associated with compliance are similar to traditional generation facilities. There is inherent flexibility in the standard requirements for the GO to determine the methodology utilized in determining the facility ratings.

To identify the facility rating of a dispersed power producing resource, the analysis of the entire suite of facility components is necessary to adequately identify the minimum and maximum Facility Rating and System Operating Limits, and thus there would be no differentiation between the compliance obligations between dispersed power producing resources and traditional generation.

The use of the term “main step-up transformer” in Requirements R1 and R2 refers to the final GSU (the last transformer(s) used exclusively for stepping up the generator output) prior to the point of interconnection or, when the point of interconnection is before the GSU, the GSU that steps up voltage to transmission line voltage level and is used strictly as a delineation point between Requirements R1 and R2. In an attempt to address this potential misinterpretation, the SDT provides the following clarifications:

1. Referencing the NERC Glossary definition of Facility Ratings identifies that the voltage, current, frequency, and real or reactive power flow through a facility must not violate the equipment rating of any equipment of the facility (that is subjected to the voltage, current, etc.). With this definition, it is clear that each component or piece of equipment must be reviewed to ensure the ratings are not exceeded, and that applicable documentation be maintained.
2. The use of the term “Facilities” in the phrase “…determining the Facility Ratings of its solely and jointly owned generator Facility(ies) up to the low side terminals of the main step-up transformer…” could potentially be interpreted to refer only to BES Facilities because the Glossary definition of “Facility” includes the term “Bulk Electric System Element.” For dispersed power producing facilities, that could leave out portions of the facility, specifically the collection system. However, the intent of the standard is to address the Facility Ratings of all electrical equipment from the generator to the point of interconnection.

As an example, for solar facilities, a GO or GOP should provide ratings for array or panel, dc cables (positive and negative), combiner boxes, and inverters, as well as associated breakers, instrument transformers (CVTs, PTs), disconnect switches, and relays, etc. This is shown in Figure A.

If there are multiple sample units comprised of a multiple of identical components with identical ratings, then only one sample unit must be provided for that piece of equipment when calculating the facility rating value. For example, if a facility is comprised of 50 identical inverter units rated at 2 MW that have identical combiner box, module string, and module compositions/orientations, then the Facility rating would be 50*2 MW = 100 MW.

In order to identify the most limiting component of the facility, a complete analysis of every component in a sample unit must be conducted. Under the assumption that the GO owns the main step-up transformer, this will include analysis from the generator (solar module or WTG) up through the high side terminals of the main step-up transformer. In an effort to simplify this analysis, grouping identical equipment configurations into a sample unit is an accepted industry practice. The following discussion and diagrams provide an explanation of how this could be accomplished for dispersed power producing resources (wind and solar).

Figure A Walk-through: For each sample unit identified, it should be clarified that a thorough rating analysis of each sample unit component must be conducted at least once to identify any potential limiting component and determine the sample unit rating. Upon completion of this analysis and arrival at a rating value, future representations of the sample unit would then be able to utilize this calculated sample unit rating as opposed to reiterating the individual component analysis.

Sample Unit #1: This sample unit is comprised of the 250 W solar modules, combiner box "A," conductors, and other electrical equipment from the solar module to, but not including, the inverter. This sample unit encompasses three strings. In order to be referenced as a sample unit in future occurrences, this exact configuration must be met (three strings, same type and number of modules, same conductor type and configuration, and same electrical components).

Sample Unit #2: This sample unit is limited to an individual string and its components (eight 250 W modules and conductors) up to the combiner box "B." The middle string (without dotted line) associated with combiner box B is actually a second instance of the Sample Unit #2 and thus would not need a separate rating analysis and would instead be represented as a multiple of Sample Unit #2 in the overall rating analysis.

Sample Unit #3: This sample unit is also limited to a single string and its components up to combiner box B. While this string utilizes the same type of solar module (250 W) as Sample Unit #2, there are fewer modules in this string, which differentiates this string from Sample Unit #2 and thus requires this string to be represented separately.
Note that combiner box B is not included in either Sample Unit #2 or #3 and thus would need to be rated separately.

Sample Unit #4: This sample unit is limited to an individual string and its components (eight 300 W modules and conductors) up to the combiner box "C." The upper string (without dotted line) associated with combiner box C is actually a third instance of the Sample Unit #2. The lower string (without dotted line) associated with combiner box C is actually a second instance of the sample unit #4. Note that combiner box C is not included in any sample unit and thus would need to be rated separately.

Sample Unit #5: This sample unit is similar to the sample unit #1 configuration but utilizes 300W modules instead of 250W modules thus would need a separate rating analysis.

Sample Unit #6: This sample unit represents all the components and sample units leading up to, and including, the inverter. The lower right-hand section of Figure A shows that the inverter that comprises

these various sample units is one of four identical units that feed into a substation bus. Thus, since the rating of this inverter has been identified as 80 kW (from manufacturer) and all the components have previously been thoroughly analyzed, the other three identical units can be represented as other instances of sample unit #6.

Sample Unit #7: This sample unit represents an inverter and/or component configuration that is different from sample unit #6. This scenario, in which the inverter in this sample unit is identical to the inverter utilized in sample unit #6, but the underlying component configuration is different from in Sample Unit #6, necessitates representation of this sample unit separately from Sample Unit #6.

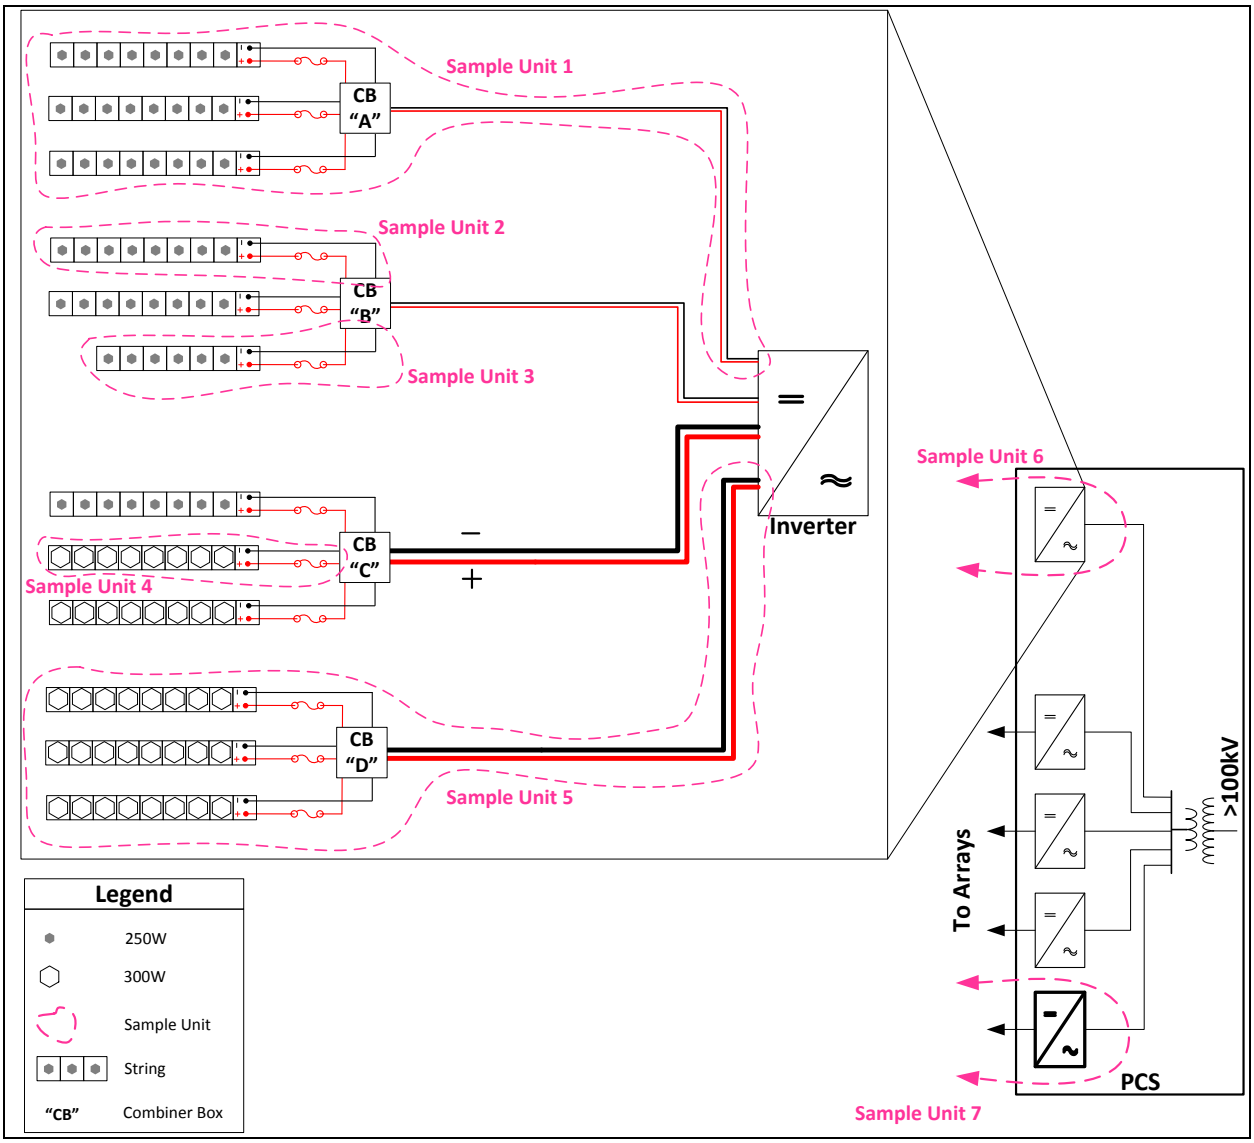

Figure A: Sample Unit Representation (Solar)

Once a complete analysis of the sample unit is conducted, this sample unit can then be referred to in future rating analyses without repeating the complete sample unit analysis. This scenario is illustrated in Table A below.

Table A:

Element	Unit Rating	#Units in system	Rating
Sample Unit #1 (Nine strings of eight 250 W modules each)	18 kW	1	18 kW
Sample Unit #2 (Three strings of eight 250 W modules)	6 kW	3	18 kW
Sample Unit #3 (Three strings of six 250 W modules)	4.5 kW	1	4.5 kW
Sample Unit #4 (Three strings of six 300 W modules)	5.4 kW	2	10.8 kW
Sample Unit #5 (Nine strings of eight 300 W modules each)	21.6 kW	1	21.6 kW
Sample Unit #6	80 kW	4	320 kW
Sample Unit #7	80 kW	1	80 kW

Figure B Walk-through: For each sample unit identified, it should be clarified that a thorough rating analysis of each sample unit component and all other serial components through to the point of interconnection must be conducted once to identify any potential limiting component and determine the sample unit rating. Upon completion of this analysis and arrival at a rating value, future representations of the sample unit would then be able to utilize this calculated sample unit rating as opposed to reiterating the individual component analysis.

Sample Unit #1: This sample unit is comprised of the Manufacturer "A" wind turbines (WTG) rated at 2.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of four WTGs. In order to be referenced as a sample unit in future occurrences, this exact configuration must be met (same type and number of WTGs, same step-up transformer, same conductor type and configuration, and same electrical components).

Sample Unit #2: This sample unit is comprised of the Manufacturer "A" wind turbines (WTG) rated at 2.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of six WTGs. The different number of WTGs in this string versus those in the sample unit #1 necessitates a separate consideration from the sample unit #1.

Sample Unit #3: This sample unit is comprised of the Manufacturer "B" wind turbines (WTG) rated at 3.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of four WTGs.

Sample Unit #4: This sample unit is comprised of the Manufacturer "B" wind turbines (WTG) rated at 3.0 MW, the associated step-up transformer, and conductors and other electrical equipment from the WTG to, but not including, the junction box. This sample unit encompasses a string of six WTGs. The different number of WTGs in this string versus in the sample unit #3 necessitates a separate consideration from the sample unit #3.

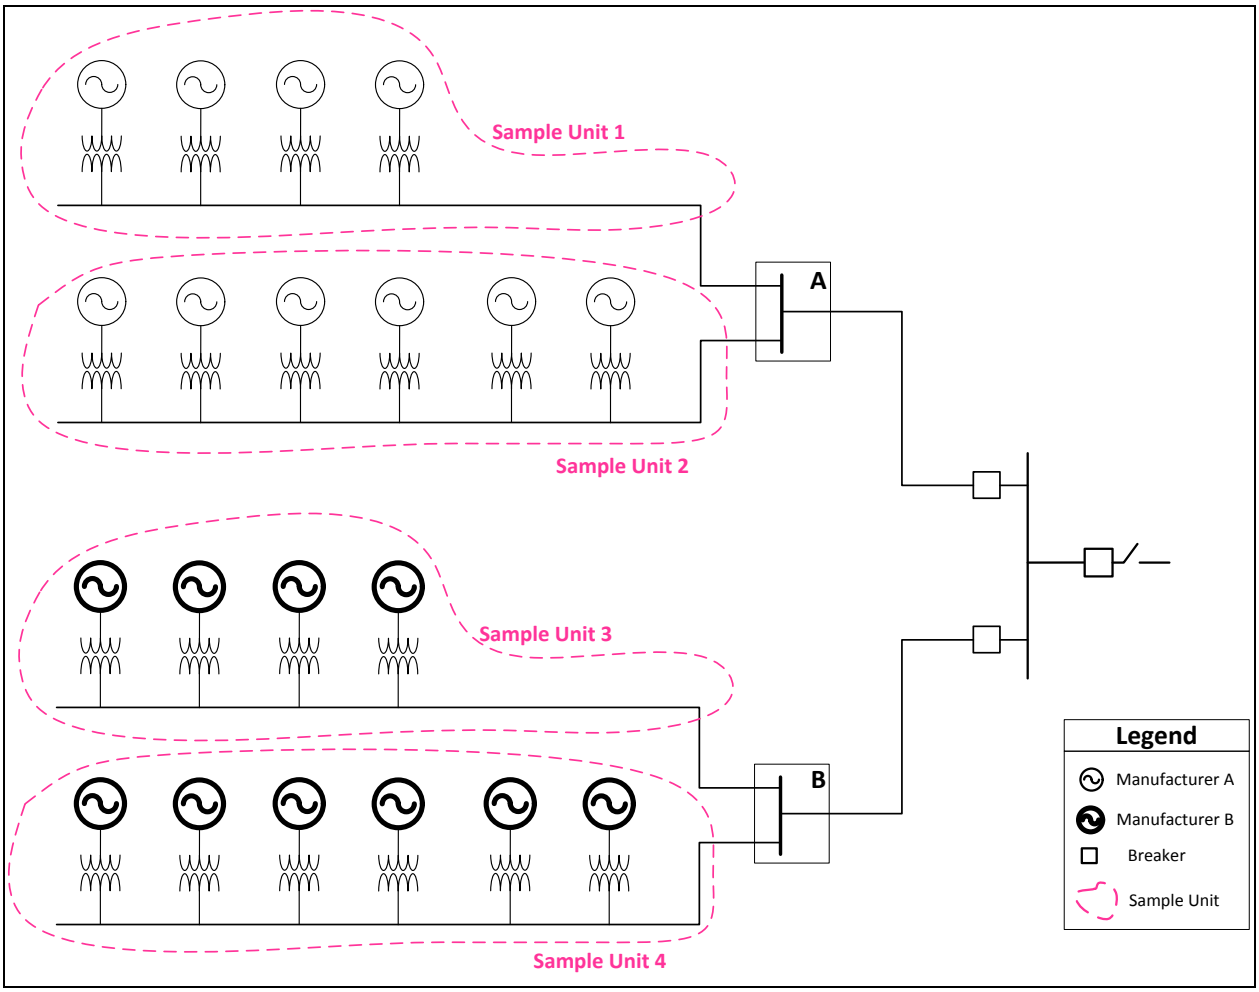

Figure B: Sample Unit Representation (Wind)

4.5 INT

The INT standards provide BAs the authority to monitor power interchange between Balancing Authority Areas. No INT standard is applicable to the GO or GOP, or affects the interaction of a host BA, TOP, or RC with individual BES Elements. *Therefore, the applicability of the INT standards does not need to be changed for dispersed power producing resources.*

4.6 IRO

The IRO standards provide RCs their authority. Three IRO standards apply directly to GO and/or GOP entities. Three standards apply to the interaction of the RC with individual BES Elements. No other IRO standard reviewed affected the interaction of a host BA, TOP, or RC with GOs and/or GOPs.

4.6.1 IRO-001 — Reliability Coordination — Responsibilities and Authorities[18]

The purpose of these standards and their requirements as applicable to a GOP is to ensure RC directives are complied with so long as they do not violate safety, equipment, or regulatory or statutory requirements, or cannot be physically implemented. If a GOP is unable to follow an RC directive, it is to inform the RC immediately.

Directives from RCs have been traditionally applied to the dispersed power producing resource at the aggregate Facility level when they are related to either active power or voltage, such as an output reduction or the provision of voltage support. When such directives are not specific to any one Element within the Facility, it is up to the GOP to determine the appropriate method to achieve the desired result of the directive consistent with other applicable NERC Reliability Standards. When an RC directive specifies a particular Element or Elements at the GOP's Facility, it is the expectation and requirement that the GOP will act as directed, so long as doing so does not violate safety, equipment, or regulatory or statutory requirements or cannot be physically implemented. For example, a directive could specify operation of a particular circuit breaker at a GOP Facility. *For these reasons, the applicability of IRO-001 does not need to be changed for dispersed power producing resources.*

4.6.2 IRO-005 — Reliability Coordination — Current Day Operations[19]

The purpose of this standard and its requirements as they relate to GOPs is to ensure that when there is a difference in derived limits, the BES is operated to the most limiting parameter. A difference in derived limits can occur on any Element; therefore, any limitation of the applicability of this standard may create a reliability gap. There is no need to differentiate applicability to dispersed generation resources from any other GOP resources. *Therefore, the applicability of IRO-005 does not need to be changed for dispersed power producing resources.*

[18] Note that IRO-001-3, which is adopted by the Board, was included in the proposed remand by FERC and is subject to revision as part of Project 2014-3 – Revisions to TOP and IRO Standards.
[19] Note that applicability to GOPs has been removed in IRO-005-4, which is adopted by the Board. However, this standard was included in the proposed remand by FERC and is subject to revision as part of Project 2014-3 – Revisions to TOP and IRO Standards.

4.6.3 IRO-010 — Reliability Coordinator Data Specification and Collection

The purpose of this standard and its requirement(s) as it relates to GOs and GOPs is to ensure data and information specified by the RC is provided. As each RC area is different in nature, up to and including the tools used to ensure the reliability of the BPS, a one-size-fits-all approach is not appropriate. This Reliability Standard allows the RC to specify the data and information required from the GO and/or the GOP, based on what is required to support the reliability of the BPS. *Therefore, the applicability of IRO-010 does not need to be changed for dispersed power producing resources.*

4.7 MOD

The MOD standards ensure consistent modeling data requirements and reporting procedures. The MOD standards provide a path for Transmission Planners (TPs) and Planning Coordinators (PCs) to reach out to entities for specific modeling information, if required. The SDT believes the existing and proposed modeling standards are sufficient for modeling dispersed power producing resources. However, due to the unique nature of dispersed power producing resources and an effort to bring consistency to the models, *the SDT believes additional guidance on the MOD standards would be beneficial and will communicate its determination to the NERC Planning Committee.*

4.7.1 MOD-010 — Steady-State Data for Transmission System Modeling and Simulation

This standard is anticipated to be retired in the near future. There is no need to differentiate dispersed generation resources from any other GOP resources as discussed in 5.7.8 regarding MOD-032. *Therefore, the applicability of MOD-010 does not need to be changed for dispersed generation resources.*

4.7.2 MOD-012 — Dynamics Data for Transmission System Modeling and Simulation

This standard is anticipated to be retired in the near future. There is no need to differentiate dispersed generation resources from any other GOP resources as discussed in 5.7.8 regarding MOD-032. *Therefore, the applicability of MOD-012 does not need to be changed for dispersed generation resources.*

4.7.3 MOD-024-1 — Verification of Generator Gross and Net Real Power Capability

This standard was established to ensure accurate information on generator gross and net Real Power capability is available for steady-state models used to assess BES reliability. This standard will be superseded by MOD-025-2.[20] *Therefore, the applicability of MOD-024-1 does not need to be changed for dispersed generation resources.*

4.7.4 MOD-025-1 — Verification of Generator Gross and Net Reactive Power Capability

This standard was established to ensure accurate information on generator gross and net Reactive Power capability is available for steady-state models used to assess BES reliability. This standard will be superseded by MOD-025-2. *Therefore, the applicability of MOD-025-1 does not need to be changed for dispersed generation resources.*

[20] MOD-024-1 and MOD-025-1 are Board-adopted but not subject to enforcement. They are commonly followed as good utility practice.

4.7.5 MOD-025-2 — Verification and Data Reporting of Generator Real and Reactive Power Capability and Synchronous Condenser Reactive Power Capability

The purpose of MOD-025-2 is to ensure that accurate information on generator gross and net Real and Reactive Power capability is available for planning models used to assess BES reliability. This standard is appropriate for and includes specific provisions for dispersed generation resources to ensure changes in capabilities are reported. *Therefore, the SDT is further evaluating whether to revise the applicability of the standard to align the language with the revised BES definition.*

4.7.6 MOD-026 — Verification of Models and Data for Generator Excitation Control System or Plant Volt/VAR Control Functions

This standard provides for verification of models and data for voltage control functions. This standard is appropriate for dispersed generation resources. *Originally, the DGR SDT considered clarifying the applicability of the Facilities section; however, upon further review, the DGR SDT recommends no change.*

4.7.7 MOD-027 — Verification of Models and Data for Turbine/Governor and Load Control or Active Power/Frequency Control Functions

This standard was established to verify that the turbine/governor and frequency control model accurately represents generator unit Real Power response to system frequency variations. This standard is appropriate for dispersed generation resources. *Originally, the DGR SDT considered clarifying the applicability of the Facilities section; however, upon further review, the DGR SDT recommends no change.*

4.7.8 MOD-032 — Data for Power System Modeling and Analysis

The MOD-032 standard was established to ensure consistent modeling data requirements and reporting procedures for the planning horizon cases. The nature of dispersed generation resources is a challenge in modeling the steady-state and dynamic electrical properties of the individual components (e.g., individual units, collector system, interconnection components, etc.).

Models for dispersed power producing resources are typically proprietary and unique for each Facility. Generic models exist for dynamic analysis that may provide sufficient accuracy in lieu of a Facility-specific model. Some sections of MOD-032 Attachment 1 pertain to modeling individual units, which may not be feasible. Guidance should be provided to show how to best model dispersed power producing resources. Such guidance should require modeling requirements for each type of dispersed power producing resource within a Facility and aggregate model for each reasonable aggregation point. *The applicability of MOD-032 does not need to be changed for dispersed power producing resources.*

4.8 NUC

The requirements in standard NUC-001, Nuclear Plant Interface Coordination, individually define the applicability to registered entities, not to the Elements the entities own or operate. While it is unlikely any Elements that are part of a dispersed power producing resource would be subject to an agreement required by this standard, limiting the applicability of this standard could create a reliability gap, and thus there is

no need to differentiate applicability to dispersed generation resources. *Therefore, the applicability of the NUC standard does not need to be changed for dispersed power producing resources.*

4.9 PER

The PER standards focus on operator personnel training. The only requirements in any of the current or future enforceable standards that apply to the GOP is requirement R6 in PER-005-2, Operations Personnel Training, and it is clearly intended to apply to the individual GOP registered functional entity that controls a fleet of generating facilities, not the constituent Elements it operates. As such, there is no need to differentiate dispersed power producing resources from any other GOP resources. *Therefore, the applicability of the PER standards does not need to be changed for dispersed power producing resources.*

4.10 PRC

The PRC standards establish guidance to ensure appropriate protection is established to protect the BES.

4.10.1 PRC-001-1.1 — System Protection Coordination

Requirement R1 requires GOPs to be familiar with the purpose and limitations of Protection System schemes applied in their area. The recently approved changes to the BES definition extend the applicability of this requirement. Often this familiarity is provided to GOP personnel through training on the basic concepts of relay protection and how it is utilized. The basic relaying concepts utilized in protection on the aggregating equipment at a dispersed generation site typically will not vary significantly from the concepts used in Protection Systems on individual generating units.

Requirement R2 requires that GOPs report protective relay or equipment failures that reduce system reliability. Protective System failures occurring within a single individual generating unit at a dispersed power producing resource will not have any impact on overall system reliability, and thus it should not be necessary for GOPs to report these failures to their TOPs and host BAs. Only failures of Protection Systems on aggregating equipment have the potential to impact BPS reliability and may require notification. When interpreted as stated above, no related changes should be required to the existing PRC-001-1 standard, as the BES definition changes do not have an impact on these requirements.

Requirement R3 requires GOPs to coordinate new protective systems. Coordinating new, and changes to existing, protective relay schemes should be applied to aggregating equipment protection only if a lack of coordination could cause unintended operation or non-operation of an interconnected entity's protection, thus potentially having an adverse impact to the BPS. Existing industry practice is to share/coordinate the protective relay settings on the point of interconnect (e.g., generator leads, radial generator tie-line, etc.) and potentially the main step-up transformer, but not operating (collection) buses, collection feeders, or individual generator protection schemes, as these Protection Systems do not directly coordinate with an interconnected utility's own Protection Systems. Relay protection functions such as under- and over frequency and under- and overvoltage changes are independent of the interconnected utility's protective relay settings, and the setting criteria are defined in PRC-024.

Requirement R5 requires GOPs to coordinate changes in generation, transmission, load, or operating conditions that could require changes in the Protection Systems of others. A GOP of a dispersed

generation resource should be required to notify its TOP of changes to generation, transmission, load, or operating conditions on an aggregate Facility level.

Project 2007-06 – System Protection Coordination and Project 2014-03 – Revisions to TOP and IRO Standards are presently revising various aspects of this standard or addressing certain requirements in other standards.

For these reasons, the DGR SDT coordinated with the other SDTs currently reviewing this standard and recommended revisions to Requirement R3.1 to indicate that coordination by a GOP with its TOP and host BA of new, or changes to, protection systems on individual generating units of dispersed power producing resources is not required.

4.10.2 PRC-001-2 — System Protection Coordination

The concerns addressed with PRC-001-1.1b are removed in PRC-001-2, which is adopted by the Board. However, this standard was included in the proposed remand by FERC and is subject to revision as part of Project 2014-03 – Revisions to TOP and IRO Standards. This standard version is not in effect and was withdrawn as the proposed versions of the TOP and IRO Reliability Standards included in Project 2014-3 effectively replace PRC-001-2 and other TOP standards. *For this reason, no changes are required.*

4.10.3 PRC-002-NPCC-01 — Disturbance Monitoring
PRC-018-1 — Disturbance Monitoring Equipment Installation and Data Reporting

Requirements related to installation of Fault/Disturbance monitoring and/or sequence of events (SOE) recording capabilities on generating units and substation equipment which meet regional specific criteria may require installation of these capabilities on the aggregating equipment at a dispersed power producing resource Facility, and requires maintenance and periodic reporting requirements to their RRO. However, these requirements have been previously applicable to the aggregating equipment at these dispersed power producing resources, and these capabilities are not required to be installed on the individual generating units. The BES definition changes have no direct impact on applicability of these standards to dispersed power producing resources. *Therefore, the applicability of these standards does not need to be changed for dispersed power producing resources.*[21]

4.10.4 PRC-004-2.1a — Analysis and Mitigation of Transmission and Generation Protection System Misoperations
PRC-004-3 — Protection System Misoperation Identification and Correction

Misoperation reporting per PRC-004 is currently a requirement applied on the aggregating equipment at applicable dispersed power producing resource sites that meet BPS criteria. The continuation of this analysis and reporting on the aggregating equipment by dispersed generation resource owners can provide value to BPS reliability and should remain in place. However, based on the experience of the SDT, there is minimal impact to BPS reliability for analyzing, reporting, and developing Corrective Action Plans for each individual generating unit that trips at a dispersed power producing resource site, as the tripping of one or a small number of these units has no material impact to BPS reliability.

[21] *See* NPCC CGS-005.

Additionally, reporting of Misoperations on each individual generating unit may result in substantial and unnecessary burdens on both the dispersed generation resource owner and the Regional Entities that review and track the resulting reports and Corrective Action Plan implementations. The SDT recognizes that many turbine technologies do not have the design capability of providing sufficient data for an entity to evaluate whether a Misoperation has occurred. Furthermore, dispersed power producing resources by their nature result in each individual generating unit potentially experiencing varied power system parameters (e.g., voltage, frequency, etc.) due to varied impedances and other variations in the aggregating facilities design. This limits the ability to determine whether an individual unit correctly responded to a system disturbance.

However, the SDT maintains that Misoperations occurring on the Protection Systems of individual generation resources identified under Inclusion I4 of the BES definition do not have a material impact on BES reliability when considered individually; however, the aggregate capability of these resources may impact BES reliability if a large number of the individual generation resources (aggregate nameplate rating of greater than 75 MVA) incorrectly operated or failed to operate as designed during a system event. As such, if a trip aggregating to greater than 75 MVA occurs in response to a system disturbance, the SDT proposed requiring analysis and reporting of Misoperations of individual generating units for which the root cause of the Protection System operation(s) affected an aggregate rating of greater than 75 MVA of BES Facilities. Note that the SDT selected the 75 MVA nameplate threshold for consistency and to prevent confusion.

The SDT was also concerned with the applicability of events where one or more individual units tripped and the root cause of the operations was identified as a setting error. In this case, the requirements of PRC-004 would be applicable for any individual units where identical settings were applied on the Protection Systems of like individual generation resources identified under Inclusion I4 of the BES definition.

The SDT concluded that it is not necessary under PRC-004 to analyze each individual Protection System Misoperation affecting individual generating units of a dispersed power producing resource. *The SDT recommended changes to the applicability of this standard to require misoperation analysis on individual generating units at a dispersed power producing resource site, only for events affecting greater than 75 MVA aggregate nameplate; the SDT determined that this will ensure that common-mode failure scenarios and their potential impact on BPS reliability are appropriately addressed. The SDT's recommended changes passed industry ballot on November 6, 2014, were approved by the Board on November 13, 2014, and are currently pending regulatory approval.*

4.10.5 PRC-004-WECC-1 — Protection System and Remedial Action Scheme Misoperation

Dispersed power producing resource sites typically would not be associated with a WECC Major Transfer Path or Remedial Action Scheme (RAS), and thus would not be affected by PRC-004-WECC-1. If a site were to be involved with one of these paths or schemes, it is likely that associated protection or RAS equipment would be located on the aggregating equipment rather than the individual generating units. As such, the BES definition changes may have an impact on applicability of this standard to dispersed power producing resources. This standard should be modified to clarify the applicability for dispersed generation resources; however, this is a regional standard and not part of the SDT's scope. *Therefore, the SDT recommends that the relevant Region evaluate the standard for modification.*

4.10.6 PRC-005-1.1b — Transmission and Generation Protection System Maintenance and Testing

The SDT recognizes that PRC-005-1.1b will be phased out beginning in early 2015. Therefore, the SDT recommends only guidance on PRC-005-1.1b rather than suggesting language changes to the standard. *Therefore, the SDT does not recommend revising the applicability of this standard for dispersed generation resources. Rather, the SDT provided recommendations for revisions to the applicable RSAW to NERC staff, which NERC has implemented after consultation with the Regions.*

4.10.7 PRC-005-2 — Protection System Maintenance
PRC-005-3 — Protection System and Automatic Reclosing Maintenance
PRC-005-4 — Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance

In some cases, the aggregated capability of the individual generating units may contribute to the reliability of the BPS; as such, there can be reliability benefit from ensuring that certain BES equipment utilized to aggregate the individual units to a common point of connection are operated and maintained as required in PRC-005. When evaluated individually, however, the generating units themselves do not have the same impact on BPS reliability as the system used to aggregate the units. The unavailability or failure of any one individual generating unit would have a negligible impact on the aggregated capability of the Facility; this would be irrespective to whether the dispersed generation resource became unavailable due to occurrence of a legitimate fault condition or due to a failure of a control system, protective element, dc supply, etc.

The protection typically utilized in these generating units includes elements that would automatically remove the individual unit from service for certain internal or external conditions, including an internal fault in the unit. These units typically are designed to provide generation output at low voltage levels (i.e., less than 1000 V). Should these protection elements fail to remove the generating unit for this scenario, the impacts would be limited to the loss of the individual generating unit and potentially the next device upstream in the collection system of the dispersed power producing resource. However, this would still only result in the loss of a portion of the aggregated capability of the Facility, which would be equally likely to occur due to a scenario in which a fault occurs on the collection system.

Internal faults on the low-voltage system of these generating units would not be discernible on the interconnected transmission systems, as this is similar to a fault occurring on a typical utility distribution system fed from a substation designed to serve customer load. It is important to note that the collection system equipment (e.g., breakers, relays, etc.) used to aggregate the individual units may be relied upon to clear the fault condition in both of the above scenarios, which further justifies ensuring portions of the BES collection equipment is maintained appropriately.

For this reason, activities such as Protection System maintenance on each individual generating unit at a dispersed generation Facility would not provide any additional reliability benefits to the BPS, but Protection System maintenance on facilities where generation aggregates to 75 MVA or more would. The SDT proposes that the scope of PRC-005 be limited to include only the protection systems that operate at a point of aggregation above 75 MVA nameplate rating. If the aggregation point occurs at a component in the collection system, then the protection systems associated with this component would be in scope. *The SDT has recommended changes to the Applicability Section (Facilities) of PRC-005-2, -3, and -4 to indicate that maintenance activities should only apply on the aggregating equipment at or above the point where the aggregation exceeds 75 MVA. The Board approved the SDT's recommended applicability changes to PRC-005-2 and PRC-005-3 on November 13, 2014. The SDT's recommended applicability changes to PRC-005-4 are pending Board approval.*

4.10.8 PRC-006-NPCC-1 — Automatic Underfrequency Load Shedding
PRC-006-SERC -1 — Automatic Underfrequency Load Shedding Requirements

The regional specific PRC-006 standards deviate from the PRC-006-1 standard in that they have specific requirements for GOs. In particular, the NPCC version requires that GOs set their underfrequency tripping to meet certain criteria to ensure reliability of the BPS. Typically, a dispersed generation resource site may have underfrequency protection on both the aggregating equipment (i.e., collection buses or feeders) and the individual generating units. If this standard were only to apply to aggregating equipment, the net impact to the BPS should a system disturbance occur may still result in a loss of significant generating capacity if each of the individual generating units trip for the event. Therefore, it may be appropriate to include the individual generating units at a dispersed generation resource site as subject to this standard. The standard could be interpreted this way as written, but further clarification in the standard language may be considered. While this standard may need to be modified to clarify the applicability for dispersed generation resources, this is a regional standard and not part of the SDT's scope. *Therefore, the SDT recommends that the relevant Region evaluate the standard for modification.*

The SERC version of PRC-006 requires GOs to provide, upon request, certain under and overfrequency related set points and other related capabilities of the site relative to system disturbances. It may be appropriate to include the capabilities of the individual generating units at a dispersed generation resource site when providing this information; however, it may be sufficient to provide only the capabilities of a single sample unit within a site, as these units are typically set identically. This would be in addition to any related capabilities or limitations of the aggregating equipment as well. This may be accomplished by providing clarifications in the requirements sections. While this standard may need to be modified to clarify the applicability for dispersed power producing resources, this is a regional standard and not part of the SDT's scope. *Therefore, the SDT recommends that the relevant Region evaluate the standard for modification.*

4.10.9 PRC-015 — Special Protection System Data and Documentation
PRC-016 — Special Protection System Misoperations
PRC-017 — Special Protection System Maintenance and Testing

Relatively few dispersed power producing resources own or operate Special Protection Systems (SPSs); however, they do exist and therefore need to be evaluated for applicability based on the revised BES definition. The vast majority of these SPSs involve the aggregating equipment (transformers, collection

breakers, etc.) and not the individual generating units. The SPSs are installed to protect the reliability of the BPS and, as such, the aggregated response of the site (e.g., reduction in output, complete disconnection from the BES, etc.) is critical—not the response of individual generating units. *Therefore, the applicability of these standards does not need to be changed for dispersed power producing resources.*

4.10.10 PRC-019-1 — Coordination of Generating Unit or Plant Capabilities, Voltage Regulating Controls, and Protection

Dispersed power producing resources typically utilize a site-level voltage control scheme that directs the individual generating units to adjust their output to meet the voltage requirements at an aggregate Facility level. In these cases, the individual generating units will simply no longer respond once they are "maxed out" in providing voltage or reactive changes, but also need to be properly coordinated with protection trip settings on the aggregating equipment to mitigate the risk of tripping in this scenario. Facilities that solely regulate voltage at the individual unit also need to consider the Protection Systems at the individual units and their compatibility with the reactive and voltage limitations of the units. The applicability in PRC-019-1 (section 4.2.3) includes a "Generating plant/Facility consisting of one or more units that are connected to the Bulk Electric System at a common bus with total generation greater than 75 MVA (gross aggregate nameplate rating)." *Therefore, the DGR SDT revised the Facilities section of the standard to clarify that facilities which solely regulate voltage at the individual generating unit are subject to this standard's requirements. The SDT's recommended applicability changes to PRC-019-1 were filed with FERC March 13, 2015.*

4.10.11 PRC-023— Transmission Relay Loadability

Dispersed power producing resources in some cases contain facilities and Protection Systems that meet the criteria described in the Applicability section (e.g., load-responsive phase Protection System on transmission lines operated at 200 kV or above); however, in the majority of cases these lines are radially connected to the remainder of the BES and are excluded from the standard requirements of PRC-023-3. While certain entities with dispersed power producing resources are required to meet the requirements of PRC-023 on components of their aggregating equipment (e.g., main step-up transformers, interconnecting transmission lines), the standard is not applicable to the individual generating units, as the individual generating units are addressed in PRC-025. The BES definition changes have no direct impact on the applicability of this standard to dispersed power producing resources. *Therefore, the applicability of this standard does not need to be changed for dispersed power producing resources.*

4.10.12 PRC-024— Generator Frequency and Voltage Protective Relay Settings

If the individual generating units at a dispersed power producing resource were excluded from this requirement, it is possible large portions or perhaps the entire output of a dispersed power producing resource site may be lost during certain system disturbances, negatively impacting BES reliability. The SDT has determined it is appropriate to require that protective relay settings applied on both the individual generating units and aggregating equipment (including any non-BES collection system equipment) are set respecting the "no-trip zone" referenced in the requirements to maintain reliability of the BES. However, for the purpose of compliance evidence, the SDT believes it should be sufficient for an entity to provide evidence for a single sample generating unit within a site rather than providing documentation for each individual unit, providing the entity used that methodology to set its protection

systems for all the units, rather than providing documentation for each individual unit. This would be in addition to any Protection System settings evidence for the aggregating equipment. *The SDT therefore recommended changes to the standard requirements to ensure these requirements are applied to the individual power producing resources as well as all equipment, potentially including non-BES equipment, from the individual power producing resource up to the point of interconnection and communicated compliance evidence requirement considerations to NERC staff for RSAW development. The SDT's recommended applicability changes to PRC-024 were filed with FERC March 13, 2015.*

4.10.13 PRC-025— Generator Relay Loadability

The Protection System utilized on individual generating units at a dispersed power producing Facility may include load-responsive protective relays and thus would be subject to the settings requirements listed in this standard. If this standard were only to apply to aggregating equipment, the net impact to the BPS if a system disturbance were to occur may be a loss of significant generating capacity if each of the individual generating units trips for the event. The SDT has determined it is appropriate to require that Protection System settings be applied on both the individual generating units at a dispersed power producing resource site as applicable to this standard. However, for the purpose of compliance evidence, the SDT believes it should be sufficient for an entity to provide evidence for a single sample generating unit within a site rather than providing documentation for each individual unit, providing the entity used that methodology to set its protection systems for all the units, rather than providing documentation for each individual unit. This would be in addition to any Protection System settings evidence for the aggregating equipment. As such, the SDT recommends the RSAW be modified as stated above. *The SDT recommended no changes to the standard; however, the DGR SDT communicated compliance evidence requirement considerations to NERC staff for RSAW development.*

4.11 TOP

The TOP standards provide TOPs their authority. Four TOP standards apply directly to GO and GOP entities. The TOP standards as they relate to GOs/GOPs ensure RCs and TOPs can issue directives to the GOP, and the GOP follows such directives. They also ensure GOPs render all available emergency assistance as requested. Finally, they require GO/GOPs to coordinate their operations and outages and provide data and information to the BA and TOP. No TOP standard refers to the interaction of a host BA, TOP, or RC with individual BES Elements.

4.11.1 TOP-001-1a — Reliability Responsibilities and Authorities

This standard as it applies to GOPs is reviewed at the requirement level, with only one change recommended.

4.11.1.1 Requirement R3

The purpose of Requirement R3 as it relates to GOPs is to ensure the RC and TOP reliability directives are complied with so long as they do not violate safety, equipment, or regulatory or statutory requirements. If a GOP is unable to follow an RC or TOP reliability directive, they are to inform the RC or TOP immediately. The requirement is applicable to the registered functional entity, not the constituent

Elements it operates. *Therefore, there is no need to differentiate applicability to dispersed power producing resources from any other GOP resources, and no change to this requirement is needed.*

4.11.1.2 Requirement R6

The purpose of Requirement R6 as it relates to GOPs is to ensure all available emergency assistance to others as requested, unless such actions would violate safety, equipment, or regulatory or statutory requirements. The requirement is applicable to the registered functional entity, not the constituent Elements it operates. *Therefore, there is no need to differentiate applicability to dispersed power producing resources from any other GOP resources, and no change to this requirement is needed.*

4.11.1.3 Requirement R7

The purpose of Requirement R7 as it relates to GOPs is to ensure BES facilities are not removed from service without proper notification and coordination with the TOP and, when time does not permit such prior notification and coordination, notification and coordination shall occur as soon as reasonably possible. This is required to avoid burdens on neighboring systems. It should be noted that the purpose of this standard is to keep the TOP informed of all generating Facility capabilities in case of an emergency. It is assumed that required notification and coordination from the GOP to the TOP would be done in real time and through verbal communication media. The concern here is how to apply this to a dispersed power producing resource Facility. The SDT recommends that the GOP report at the aggregate Facility level to the TOP any generator outage above 20 MVA for dispersed power producing resource facilities. The justification is based on the following:

- This is consistent with Inclusion I2 of the revised BES definition, which addresses only generating units greater than 20 MVA.
- TOP-002-2.1b Requirement R14 requires real-time notification of changes in Real Power capabilities, planned and unplanned. Setting the threshold at 20 MVA would address routine maintenance on a small portion of the Facility (e.g., 2% of the generators are out of service on any given day) and individual generating units going into a failure. Otherwise, coordinating each individual generating unit outage would burden the TOP without providing an increase in reliability to the interconnected BPS.

Dispersed power producing resource outages should be reported as "x MW out of y MW are available." *Therefore, the SDT recommends that a modification to the applicability of this requirement is necessary for dispersed power producing resources for generator outages greater than 20 MVA.*

4.11.2 TOP-001-3 — Transmission Operations[22]

The purpose of this standard as it relates to GOPs is to ensure TOP directives are complied with so long as they do not violate safety, equipment, or regulatory or statutory requirements. If a GOP is unable to follow a TOP directive, it is to inform the TOP immediately. It directs the TOP to issue directives, and as such, the TOP may provide special requirements for dispersed power producing resources for its unique

[22] Note that TOP-001-2 was adopted by the Board and remanded by FERC. TOP-001-2 is currently under revision as part of Project 2014-03 – Revisions to TOP and IRO Standards, and was posted for additional ballot period that is scheduled to close January 7, 2015 as TOP-001-3.

capabilities. *The SDT recommended that Project 2014-3 provide direction for a dispersed power producing resource to be only reported at the aggregate facility level.*

4.11.3 TOP-002-2.1b — Normal Operations Planning[23]

This TOP standard has five requirements applied to GOPs. Several modifications are recommended below, and the SDT recommends that the most effective and efficient way to accomplish this is through modification of the Applicability section of this standard.

4.11.3.1 Requirement R3

The purpose of Requirement R3 as it relates to GOPs is to ensure a GOP's current-day, next-day and seasonal operations are coordinated with its host BAs and TSP. This requirement relates to planned operations at a generator and does not include unplanned operations such as forced or emergency operations. The SDT recommends that this requirement be applied at the aggregate Facility level for dispersed power producing resources. For example, forecasting available megawatts at the aggregated Facility level is currently one method used. The SDT does not see any reliability gap that would prompt this team to apply R3 to any point less than the dispersed power producing resource aggregated Facility level.

The SDT has not found or been made aware of a reliability gap that would prompt this team to apply R3 to any point less than the dispersed power producing resource aggregated Facility level and recommends such modification to the applicability of this requirement.

4.11.3.2 Requirement R13

The purpose of Requirement R13 as it relates to GOPs is to ensure Real Power and Reactive Power capabilities are verified as requested by the BA and TOP. The SDT believes a modification to the applicability of this requirement is necessary for dispersed power producing resources. The SDT recommends that this requirement be applied at the aggregate Facility level for dispersed power producing resources for the following reasons:

- Due to the nature, amount of individual generators at a dispersed power producing resource, internal Real Power losses, and natural inductance and capacitance of dispersed power resource system connected in series, verification of real and reactive capabilities should be conducted at the dispersed power producing resource aggregate Facility level. Performing verification in this manner will provide an actual net real and reactive capability, which would be seen by both the BA and TOP. In addition, performing verification in this manner is also consistent with operating agreements such as an interconnection agreement, which the dispersed power resource has with the TOP and BA.
- MOD-025-2 also provides that verification for any generator less than 20 MVA may be completed on an individual unit basis or as a "group." Reporting capability at the aggregated Facility level is consistent with the MOD-025-2 provision for group verification.

[23] The GOP applicability is removed in TOP-002-3, which was adopted by the Board. However, TOP-002-3 was included in the proposed remand by FERC and is subject to revision as part of Project 2014-3 – Revisions to TOP and IRO standards.

The SDT recommends a modification to the applicability of this requirement at the aggregated Facility level for dispersed power producing resources.

4.11.3.3 Requirement R14

The purpose of Requirement R14 as it relates to GOPs is to ensure BAs and TOPs are notified of changes in real output capabilities without any intentional time delay. It should be noted that the purpose of this requirement is to address unplanned changes in real output capabilities. It is assumed the required notification and coordination from the GOP to the BA and TOP would be done in real time and through verbal communication media. The concern here is how to apply this to dispersed power producing resources. The SDT recommends that the GOP notify at the aggregate Facility level to the TOP any unplanned changes in real output capabilities above 20 MVA. The justification is based on the following:

- This is consistent with Inclusion I2 of the revised BES definition, which includes generating units greater than 20 MVA; and
- TOP-002-2.1b R14 requires real-time notification of changes in Real Power capabilities, planned and unplanned. Setting the threshold at 20 MVA would address routine maintenance on a small portion of the Facility (e.g. 2% of the generators are out of service on any given day) and individual generating units going into a failure. Otherwise, coordinating each individual generating unit outage would burden the TOP without providing an increase in reliability to the interconnected BPS.

Changes in the real output capabilities of dispersed generation resources should be reported as "x MW out of y MW are available." *The SDT recommends that a modification to the applicability of this requirement is necessary for dispersed power producing resources for unplanned outages greater than 20 MVA.*

4.11.3.4 Requirement R15

The purpose of Requirement R15 as it relates to GOPs is to ensure BAs and TOPs are provided a forecast (e.g., seven days) of expected Real Power. The SDT believes this requirement as requested by the BA or TOP is being applied at the aggregate Facility level for dispersed power producing resources.

Based on the SDT's experience, expected Real Power forecasts (e.g., five- or seven-day forecast) for a dispersed power producing resource traditionally have been coordinated with the BA and TOP at the aggregate Facility level for dispersed power producing resources. *Therefore, the SDT recommends that R15 be applied at the aggregate Facility level for dispersed power resources and, as such, modification to the applicability of this requirement is necessary.*

4.11.3.5 Requirement R18

The purpose of Requirement R18 as it relates to a GOP is to ensure uniform line identifiers are used when referring to transmission facilities of an interconnected network. The standard applies to transmission facilities of an interconnected network, which would not apply to any Elements within the dispersed generation Facility. There is no need to differentiate applicability to dispersed generation resources from any other GOP resources. *Therefore, the applicability of this requirement does not need to be changed for dispersed generation resources.*

4.11.4 TOP-003-1— Planned Outage Coordination

This TOP Standard has three requirements applied to GOPs. Modification to one of these requirements is recommended.

4.11.4.1 Requirement R1

The purpose of Requirement R1 as it relates to GOPs is to ensure TOPs are provided planned outage information on a daily basis for any scheduled generator outage greater than 50 MW for the next day. *Therefore, the applicability of this requirement does not need to be changed for dispersed generation resources.*

4.11.4.2 Requirement R2

The purpose of Requirement R2 as it relates to GOPs is to ensure all scheduled outages of voltage-regulating equipment are planned and coordinated with affected BAs and TOPs. A modification to the applicability of this requirement is necessary for dispersed power producing resources. The SDT recommends that this requirement be applied at the aggregate Facility level for dispersed power producing resources.
