A: Your code is in C++. My guess is that this is a translation of a Java code. To get the code into an executable form, your compiler (or the IDE) must make the following "transition" from the Java code to the C++ code: conversion of text characters to integers conversion of integers to ASCII conversion of ASCII to an alphanumeric character (e.g., English) conversion of ASCII characters to an alphanumeric character (e.g., English) conversion of alphanumeric characters to an alphabet (e.g., English) conversion of alphabets to an alphabet (e.g., English) conversion of alphabets to punctuation (e.g., English) conversion of punctuation to punctuation (e.g., English) conversion of whitespace to spaces conversion of punctuation to whitespace conversion of line breaks to newlines Note that not all the above conversions are reversible. The translations above come for free in your compiler (or IDE) if you use the right C++ dialect (e.g., C++11). Now, that you have translated your code from Java to C++, can you tell me what does this code do? How do you want the generated output to look like? For example, if you want the generated output to be English sentences, the above C++ translations might look like:

```
// input.txt 5 5 7 7 3 4 5 3 7 6 7 4 // main.cpp
#include #include #include #include int main() { // read the input from the file
std::ifstream inp("input.txt"); std::string line; // read each line while
(std::getline(inp, line)) { // remove white spaces
```
