The N-terminal region of *Paracoccus denitrificans* cytochrome c2 contains amino acid residues responsible for the binding of cytochrome c. The N-terminal fragment of cytochrome c2 from *Paracoccus denitrificans* (cytochrome c2N, residues 1-62), corresponding to the signal sequence and the heme-binding domain of the mature protein, binds cytochrome c with high affinity ($K_D = 0.6 \mu\text{M}$) and forms a 1:1 complex in solution. The C-terminal half of cytochrome c2, residues 63-161, binds cytochrome c with lower affinity ($K_D = 20 \mu\text{M}$). In the absence of the heme, cytochrome c2N and the isolated heme-binding domain bind cytochrome c with comparable affinities ($K_D = 0.3 \mu\text{M}$). However, the binding of cytochrome c by the heme-containing cytochrome c2N fragment is strictly dependent on heme, because cytochrome c has little affinity for this fragment when the heme is not bound ($K_D = 100 \mu\text{M}$). Site-directed mutagenesis has been used to identify amino acid residues involved in the binding of cytochrome c to the heme-containing domain of cytochrome c2N. The replacement of either the His-10 or the His-14 residue in the heme-binding motif with the corresponding amino acid from cytochrome c has little effect on the binding of the mutant protein to cytochrome c. The binding of cytochrome c to cytochrome c2N is greatly weakened by the replacement of either Asn-16 or Ser-25 with the corresponding amino acids of cytochrome c. The binding of cytochrome c to the heme-containing cytochrome c2N fragment is very strongly inhibited by the mutation of the Asn-16 residue to Ala or of the 2d92ce491b
