Figure S3
Hemotoxylin:Eosin stained paraffin embedded liver sections from AOiGHD and GH-intact controls. Mice were fed a standard rodent chow diet (17% kcal from fat) and tissues collected at 10 months of age (7 months after DT treatment). Within AOiGHD hepatocytes there is less open (unstained) area, as compared to GH-intact controls, indicative of less lipid accumulation. This is consistent with reduced hepatic triglyceride levels in high-fat fed AOiGHD mice (shown in Fig. 3 in main body of the text).
