

Realistic 2D quasilinear modeling of fast ion relaxation

Vinícius Duarte, Nikolai Gorelenkov, Mario Podestà and Roscoe White

Princeton Plasma Physics Laboratory, Princeton, NJ, USA

Special thanks to Raffi Nazikian, Cami Collins and the DIII-D team for providing experimental data

Fast ion transport predictions for whole device modeling are needed for fusion plasmas

DIII-D critical gradient experiments

Stiff, stochastic fast ion transport gives credence in using a quasilinear approach

C. Collins et al, PRL 2016

- Fully nonlinear modeling of fast ion interaction with Alfvénic modes in a realistic tokamak is numerically expensive
- Reduced (but still realistic) modeling can be exploited if linear mode properties do not change faster than the equilibrium, e. g.,
 - eigenstructure
 - resonance condition
- Simulations need to cope with the simultaneous excitation of multiple unstable Alfvénic instabilities
- Reduced models need to be strongly verified

Outline

- The Resonance Broadened Quasilinear (RBQ) model
- RBQ1D verification exercises
- RBQ interfacing with TRANSP
- Ongoing extension to 2D

The relevant diffusion path for particles resonating with a low-frequency Alfvénic mode is nearly 1D

Equilibrium – 3 invariants

$$\mathcal{E} = v^2/2,$$

$$\mu = \mathcal{E}_\perp / B,$$

$$P_\varphi = z\psi(R, Z)/Mc - \\ - \sigma_\parallel \sqrt{2\mathcal{E}} \sqrt{1 - \mu B/\mathcal{E}} (RB_\varphi/B),$$

Particle trajectory is one point
in $(\mathcal{E}, P_\varphi, \mu)$ space

In the presence of low-frequency perturbations:

- the invariance of μ is roughly maintained;
- the invariances of $\mathcal{E}$ and P_φ are broken
- if the ansatz $e^{-i(n\varphi + \omega t)}$ holds, a new invariant emerges:

$$\mathcal{E}' = \mathcal{E} + \omega P_\varphi / n$$

Particle motion is 1D upon
single mode interaction

Resonance broadened quasilinear (RBQ) model: motivation for the 2D generalization

- Designed to address both regimes of isolated and overlapping resonances
 - the fast ion distribution function relaxes while self-consistently evolving the amplitude of modes
 - interfaced with linear ideal/kinetic codes, NOVA/NOVA-K, which provide eigenstructures, damping rates and wave-particle interaction matrices for resonances in the constant of motion space

The ultimate goal of the SciDAC RBQ work is to evolve particle distribution in 2D in whole-device modeling

H. Berk, B. Breizman, J. Fitzpatrick, and H. Wong, Nucl. Fusion 35, 1661 (1995).

Resonance-broadened quasilinear (RBQ) diffusion model

Formulation in action and angle variables^{2,3}

- Diffusion equation:

$$\frac{\partial f}{\partial t} = \frac{\partial}{\partial I} \left(\sum_{n_k, p, m, m'} D(I; t) \right) \frac{\partial f}{\partial I} + \left(\left| \frac{\partial \Omega_1}{\partial I} \right|_{I_r} \right)^{-2} \nu_{scatt,1}^3 \frac{\partial^2 (f - f_0)}{\partial I^2}$$

- Mode amplitude evolution:

$$\frac{dC_n^2(t)}{dt} = 2(\gamma_{L,n} - \gamma_{d,n}) C_n^2(t)$$

Broadened delta, a function of $\Delta\Omega$

$$D(I; t) = \pi C_k^2(t) \mathcal{E}^2 \left(\frac{\mathcal{F}_1(I - I_r)}{\left| \frac{\partial \Omega_1}{\partial I} \right|} \right) G_{m'p}^* G_{mp}$$

$$\frac{\partial}{\partial I} = \omega \frac{\partial}{\partial \mathcal{E}} - n \frac{\partial}{\partial P_\varphi}$$

eigenstructure information

Physics-based determination of the window function is pending

Broadening is the platform that allows for momentum and energy exchange between particles and waves:

$$\Delta\Omega = a\omega_b + b\nu_{eff}$$

¹Berk, Breizman, Fitzpatrick and Wong, NF 1995.

²Kaufman PoF, JPP 1972 (no broadening due to growth rate!).

Outline

- The Resonance Broaded Quasilinear (RBQ) model
- RBQ1D verification exercises
- RBQ interfacing with TRANSP
- Ongoing extension to 2D

Verification: determining the parametric dependencies of the broadening from single mode saturation levels – collisional case

We use analytic results for determining a and b : $\Delta\Omega = a\omega_b + b\nu_{eff}$

Limit near marginal stability³
 $\rightarrow b = 3.1$

$$\omega_b = 1.18\nu_{eff} \left(\frac{\gamma_{L0} - \gamma_d}{\gamma_{L0}} \right)^{1/4}$$

Limit far from marginal stability⁴
 $\rightarrow a = 2.7$

$$\omega_b = 1.2\nu_{eff} \left(\frac{\gamma_{L0} - \gamma_d}{\gamma_d} \right)^{1/3}$$

Resonance-broadened quasilinear formalism can cope with both situations of isolated and overlapping modes

⁴H. L. Berk and B. N. Breizman. Phys. Fluids B, 2(9), 1990

Verification: RBQ replicates analytical predictions for mode saturation amplitude

Definitions: initial linear growth rate γ_L , mode damping rate γ_d and trapping (bounce) frequency ω_b (proportional to square root of mode amplitude)

Collisionless case

- Undamped case

$$\omega_b \cong 3.2\gamma_L$$

Collisional cases

- Close to marginal stability: $\nu_{\text{eff}} \gg \omega_b$

$$\omega_b = 1.18\nu_{\text{eff}} \left(\frac{\gamma_L - \gamma_d}{\gamma_d} \right)^{1/4}$$

- Far from marginal stability: $\omega_b \gg \nu_{\text{eff}}$

$$\omega_b = 1.2\nu_{\text{eff}} \left(\frac{\gamma_L - \gamma_d}{\gamma_d} \right)^{1/3}$$

Expected saturation levels from analytic theory are shown by - - -

Verification: analytical collisional mode evolution near threshold

- Near marginal stability, the wave amplitude evolution is governed by [Berk, Breizman and Pekker, PRL 1996]

$$\frac{dA(t)}{dt} = A(t) - \frac{1}{2} \int d\Gamma \mathcal{H} \left\{ \int_0^{t/2} dz z^2 A(t-z) \times \int_0^{t-2z} dy e^{-\hat{\nu}_{eff}^3 z^2 (2z/3+y)} A(t-z-y) A^*(t-2z-y) \right\}$$

- An approximate analytical solution is found when $\hat{\nu}_{eff} \gg 1$: [Duarte & Gorelenkov, NF 2019]

$$A(t) = \frac{A(0)e^t}{\sqrt{1 - gA^2(0)(1 - e^{2t})}}$$

$g \equiv \int d\Gamma \mathcal{H} \frac{\Gamma(1/3)}{6\hat{\nu}_{eff}^4} \left(\frac{3}{2}\right)^{1/3}$ is a resonance-averaged collisional contribution evaluated by NOVA-K

- Challenge: non-rectangular domain due to loss boundary
- Burning plasma modeling will be computationally expensive

Podestà, NF 2016

Verification of the 2D diffusion scheme against analytic prediction

Numerical distribution function:
unconditionally stable

Relative error does not accumulate

Scaling laws for numerical error

Grid spacing dependence

Time stepping dependence

Future verifications:

- change diffusion directions to verify against known analytic solutions;
- include multiple modes;
- explore diffusion paths in the presence of overlap;

Summary

- RBQ1D addresses both isolated and overlapping resonances
- oscillating and quasi-steady evolutions are recovered
- RBQ1D is verified against known analytical solution in limiting cases
- integration with TRANSP allows whole-device reduced modeling, which captures hollow profiles
- **Ongoing work: full 2D multi-mode resonant dynamics (with strong V&V exercises)**
