

THE 3 D's

Comparison of DEPRESSION, DELIRIUM And DEMENTIA

| | Depression | Delirium | Dementia |
|------------------------------|--|---|---|
| Definition | A change in mood which lasts at least 2 weeks and includes sadness, negativity, loss of interest, pleasure and/or decline in functioning. | An acute or sudden onset of mental confusion as a result of a medical, social, and/ or environmental condition. | Progressive loss of brain cells resulting in decline of day-to-day cognition and functioning. A terminal condition. |
| Duration | At least 6 weeks, but can last several months to years, especially if not treated. | Hours to months, dependent on speed of diagnosis. | Years (usually 8 to 20) |
| Thinking | May be indecisive and thoughts highlight failures and a sense of hopelessness. | Fluctuates between rational state and disorganized, distorted thinking with incoherent speech. | Gradual loss of cognition and ability to problem solve and function independently. |
| Mental Status Testing | Capable of giving correct answers, however often may state "I don't know" | Testing may vary from poor to good depending on time of day and fluctuation in cognition. | Will attempt to answer and will not be aware of mistakes. |
| Memory | Generally intact, though may be selective. Highlights negativity. | Recent and immediate memory impaired. | Inability to learn new information or to recall previously learned information. |
| Sleep-Wake Cycle | Disturbed, usually early morning awakening. | Disturbed. Sleep-wake cycle is reversed (up in night, very sleepy and sometimes non-responsive during the day) | Normal to fragmented |
| Hallucinations and Delusions | Can be present in a severe depression. Themes of guilt and self-loathing. | Often of a frightening or paranoid nature | Can be present. May misperceive. In Lewy Body dementia, visual hallucinations are present. |
| Diagnosis | May deny being depressed but often exhibit anxiety. Others may notice symptoms first. Increased complaints of physical illness. Social withdrawal is common. | Diagnosis based on rapid onset of fluctuating symptoms. Can be mistaken for progression of the dementia. | Usually diagnosed approximately 3 years after onset of symptoms. Must rule out other causes of cognitive decline, e.g., depression or delirium. |

| | Depression | Delirium | Dementia |
|--------------------|--|--|--|
| Care approaches | Identify the symptoms of depression early. Help person to follow treatment plan and offer them hope. | Early recognition is key. Keep person safe, find cause of the delirium and treat as quickly as possible. | Maintain and enhance abilities that remain. Focus on the positive and support the lost abilities. |
| Prognosis | Treatable and reversible condition. | Treatable and reversible with early diagnosis but can lead to permanent disability or death | Progression can be slowed but not reversed. |
| Treatment | Antidepressants, ECT, interpersonal therapy, behavioural-cognitive therapy. Assist person to improve confidence and self-esteem through conversation and activity. | Treat underlying cause. Monitor response. Be alert for relapse; occurs in 90% of cases | Cholinesterase inhibitors slow the progression of some dementias. Symptomatic treatment with environmental and staff approaches. |
