About This Guide

Purpose

The *Magnitude Simba Google BigQuery ODBC Data Connector Installation and Configuration Guide* explains how to install and configure the Magnitude Simba Google BigQuery ODBC Data Connector. The guide also provides details related to features of the connector.

Audience

The guide is intended for end users of the Simba Google BigQuery ODBC Connector, as well as administrators and developers integrating the connector.

Knowledge Prerequisites

To use the Simba Google BigQuery ODBC Connector, the following knowledge is helpful:

- Familiarity with the platform on which you are using the Simba Google BigQuery ODBC Connector
- Ability to use the data source to which the Simba Google BigQuery ODBC Connector is connecting
- An understanding of the role of ODBC technologies and driver managers in connecting to a data source
- Experience creating and configuring ODBC connections
- Exposure to SQL

Document Conventions

Italics are used when referring to book and document titles.

Bold is used in procedures for graphical user interface elements that a user clicks and text that a user types.

Monospace font indicates commands, source code, or contents of text files.

Note:

A text box with a pencil icon indicates a short note appended to a paragraph.

 Important:

A text box with an exclamation mark indicates an important comment related to the preceding paragraph.

About the Simba Google BigQuery ODBC Connector

The Simba Google BigQuery ODBC Connector enables Business Intelligence (BI), analytics, and reporting on data that has been uploaded to Google Storage. The connector complies with the ODBC 3.80 data standard and adds important functionality such as Unicode, as well as 32- and 64-bit support for high-performance computing environments on all platforms.

ODBC is one of the most established and widely supported APIs for connecting to and working with databases. At the heart of the technology is the ODBC connector, which connects an application to the database. For more information about ODBC, see *Data Access Standards* on the Simba Technologies website: <https://www.simba.com/resources/data-access-standards-glossary>. For complete information about the ODBC specification, see the *ODBC API Reference* from the Microsoft documentation: <https://docs.microsoft.com/en-us/sql/odbc/reference/syntax/odbc-api-reference>.

The Simba Google BigQuery ODBC Connector is available for Microsoft® Windows®, Linux, and macOS platforms.

The *Installation and Configuration Guide* is suitable for users who are looking to access BigQuery data from their desktop environment. Application developers might also find the information helpful. Refer to your application for details on connecting via ODBC.

Note:

For information about how to use the connector in various BI tools, see the *Simba ODBC Connectors Quick Start Guide for Windows*: http://cdn.simba.com/docs/ODBC_QuickstartGuide/content/quick_start/intro.htm.

Windows Connector

Windows System Requirements

Install the connector on client machines where the application is installed. Before installing the connector, make sure that you have the following:

- Administrator rights on your machine.
- A machine that meets the following system requirements:
 - One of the following operating systems:
 - Windows 11 or 10
 - Windows Server 2022, 2019, 2016, or 2012
 - 100 MB of available disk space

Before the connector can be used, the Visual C++ Redistributable for Visual Studio 2022 with the same bitness as the connector must also be installed. If you obtained the connector from the Simba website, then your installation of the connector automatically includes this dependency. Otherwise, you must install the redistributable manually. You can download the installation packages for the redistributable at <https://learn.microsoft.com/en-us/cpp/windows/latest-supported-vc-redist?view=msvc-170>.

Installing the Connector on Windows

If you did not obtain this connector from the Simba website, you might need to follow a different installation procedure. For more information, see the *Simba OEM ODBC Connectors Installation Guide*.

On 64-bit Windows operating systems, you can execute both 32-bit and 64-bit applications. However, 64-bit applications must use 64-bit connectors, and 32-bit applications must use 32-bit connectors. Make sure that you use a connector whose bitness matches the bitness of the client application:

- `SimbaODBCDriverforGoogleBigQuery32.msi` for 32-bit applications
- `SimbaODBCDriverforGoogleBigQuery64.msi` for 64-bit applications

You can install both versions of the connector on the same machine.

To install the Simba Google BigQuery ODBC Connector on Windows:

1. Depending on the bitness of your client application, double-click to run `SimbaODBCDriverforGoogleBigQuery32.msi` or

SimbaODBCDriverforGoogleBigQuery64.msi.

2. Click **Next**.
3. Select the check box to accept the terms of the License Agreement if you agree, and then click **Next**.
4. To change the installation location, click **Change**, then browse to the desired folder, and then click **OK**. To accept the installation location, click **Next**.
5. Click **Install**.
6. When the installation completes, click **Finish**.
7. If you received a license file through email, then copy the license file into the `\lib` subfolder of the installation folder you selected above. You must have Administrator privileges when changing the contents of this folder.

Creating a Data Source Name on Windows

Typically, after installing the Simba Google BigQuery ODBC Connector, you need to create a Data Source Name (DSN).

Alternatively, for information about DSN-less connections, see [Using a Connection String](#) on page 57.

To create a Data Source Name on Windows:

1. From the Start menu, go to **ODBC Data Sources**.

Note:

Make sure to select the ODBC Data Source Administrator that has the same bitness as the client application that you are using to connect to BigQuery.

2. In the ODBC Data Source Administrator, click the **Drivers** tab, and then scroll down as needed to confirm that the Simba Google BigQuery ODBC Connector appears in the alphabetical list of ODBC connectors that are installed on your system.
3. Choose one:
 - To create a DSN that only the user currently logged into Windows can use, click the **User DSN** tab.
 - Or, to create a DSN that all users who log into Windows can use, click the **System DSN** tab.

Note:

It is recommended that you create a System DSN instead of a User DSN. Some applications load the data using a different user account, and might not be able to detect User DSNs that are created under another user account.

4. Click **Add**.
5. In the Create New Data Source dialog box, select **Simba Google BigQuery ODBC Connector** and then click **Finish**. The Simba Google BigQuery ODBC Connector DSN Setup dialog box opens.
6. In the **Data Source Name** field, type a name for your DSN.
7. Optionally, in the **Description** field, type relevant details about the DSN.
8. From the **Encrypt Sensitive Data** drop down list, select one:
 - To encrypt and decrypt the sensitive data by all the users on the system, select **For All Users**.
 - Or, to encrypt and decrypt the sensitive data only by the system user who encrypted them, select **For Current User Only**.
9. Configure authentication using the options in the Authentication area. For more information, see [Configuring Authentication on Windows](#) on page 12.
10. To allow the connector to access Google Drive so that it can support federated tables that combine BigQuery data with data from Google Drive, select the **Request Google Drive Scope Access** check box.
11. Choose one:
 - To verify the server using the trusted CA certificates from a specific `.pem` file, specify the full path to the file in the **Trusted Certificates** field and leave the **Use System Trust Store** check box cleared.
 - Or, to use the trusted CA certificates `.pem` file that is installed with the connector, leave the default value in the **Trusted Certificates** field, and leave the **Use System Trust Store** check box cleared.
 - Or, to use the Windows Trust Store, select the **Use System Trust Store** check box and leave the **Trusted Certificates** field cleared.
12. From the **Minimum TLS** drop-down list, select the minimum version of TLS to use when connecting to your data store.
13. In the **Catalog (Project)** drop-down list, select the name of your BigQuery project. This project is the default project that the Simba Google BigQuery ODBC Connector queries against, and also the project that is billed for queries that are run using the DSN.

Note:

If you are not signed in to your Google account, then you are prompted to sign in.

14. Optionally, in the **Dataset** drop-down list, select the name of the dataset the connector will query by default. For more information, see [Dataset](#) on page 77.
15. To configure a connection through a proxy server, click **Proxy Options**. For more information, see [Configuring a Proxy Connection on Windows](#) on page 19.
16. To configure logging behavior for the connector, click **Logging Options**. For more information, see [Configuring Logging Options on Windows](#) on page 23.
17. To configure advanced connector options, click **Advanced Options**. For more information, see [Configuring Advanced Options on Windows](#) on page 20.
18. To test the connection, click **Test**. Review the results as needed, and then click **OK**.
19. To save your settings and close the Simba Google BigQuery ODBC Connector DSN Setup dialog box, click **OK**.
20. To close the ODBC Data Source Administrator, click **OK**.

Setting Connector-Wide Configuration Options on Windows

When you specify connection settings in a DSN or connection string, those settings apply only when you connect to BigQuery using that particular DSN or string. As an alternative, you can specify certain settings that apply to every connection that uses the Simba Google BigQuery ODBC Connector by configuring them in the Windows registry. For information about the Windows registry, see the Microsoft Windows documentation.

Important:

Editing the Windows Registry incorrectly can potentially cause serious, system-wide problems that may require re-installing Windows to correct.

To set connector-wide configuration options on Windows:

1. Choose one:
 - If you are using Windows 7 or earlier, click **Start** , then type **regedit** in the **Search** field, and then click **regedit.exe** in the search results.
 - Or, if you are using Windows 8 or later, on the Start screen, type **regedit**, and then click the **regedit** search result.

2. Navigate to the appropriate registry key for the bitness of your connector and your machine:

- If you are using the 32-bit connector on a 64-bit machine, then browse to the following registry key:

```
HKEY_LOCAL_
MACHINE\SOFTWARE\Wow6432Node\Simba\Simba
BigQuery ODBC Driver\Driver
```

- Otherwise, browse to the following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Simba\Simba
BigQuery ODBC Driver\Driver
```

3. For each configuration option that you want to configure as a connector-wide setting, create a value by doing the following:

- a. Right-click the **Driver** subkey and then select **New > String Value**.
- b. Type the key name of the configuration option and then press **Enter**.

To confirm the key names for each configuration option, see [Connector Configuration Properties](#) on page 73.

- c. Right-click the new value and then click **Modify**.
- d. In the Edit String dialog box, in the **Value Data** field, type the value for the configuration option.

4. Close the Registry Editor.
5. Restart your ODBC application to make sure that the new settings take effect.

The `MaxThreads` property must be configured in the `simba.googlebigqueryodbc.ini` file, or as a Windows Registry key value on Windows. For more information see [MaxThreads](#) on page 99.

Configuring Authentication on Windows

The Simba Google BigQuery ODBC Connector uses the OAuth 2.0 protocol for authentication and authorization. It authenticates your connection through Google OAuth APIs. You can configure the connector to provide your credentials and authenticate the connection to the database using one of the following methods:

- [Using a Google User Account](#) on page 13
- [Using a Google Service Account](#) on page 16
- [Using an External Account](#) on page 16
- [Using Application Default Credentials](#) on page 19

Using a Google User Account

You can configure the connector to authenticate the connection with a Google user account. This authentication method uses the OAuth 2.0 access and refresh tokens associated with the user account as the credentials.

The access token is transmitted with every API call that the connector makes, and it is required for accessing BigQuery data stores. However, the access token expires after a certain amount of time and must be renewed using the refresh token. If the refresh token is stored in your connection information, the connector automatically uses it to renew access tokens when they expire.

Note:

For more information about OAuth 2.0, see "Using OAuth 2.0 to Access Google APIs" in the Google Identity Platform documentation:
<https://developers.google.com/identity/protocols/OAuth2>.

At minimum, you need to provide the OAuth 2.0 refresh token associated with your account. The connector retrieves and uses an access token based on your specified refresh token.

- If you do not have your refresh token, see [Retrieving a Refresh Token](#) on page 13.
- If you already have your refresh token, see [Providing a Refresh Token](#) on page 15.
- If you want to provide a `.json` key file that contains your credentials instead of providing your refresh token directly in your connection information, see [Providing a Key File](#) on page 15.

Retrieving a Refresh Token

When you authenticate your connection this way, the authentication process provides a temporary confirmation code that you can exchange for an access token and a refresh token.

To configure user account authentication by retrieving a refresh token on Windows:

1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
2. From the **OAuth Mechanism** drop-down list, select **User Authentication**.
3. Click **Sign In**.

4. In the browser that opens, type your credentials for accessing your BigQuery data and sign in to your account.
5. The connector waits for two minutes (120 seconds) for the sign in to complete. While waiting for the sign in to complete, the configuration dialog will be unresponsive.
6. Click **Allow**, when you are prompted to allow the client (default client or your own client) to access your data in Google cloud with specific scopes. The connector later uses this client and generated refresh token to get an Access token. The browser will display a message indicating that the dialog successfully retrieved the refresh token.
7. The connector automatically populates the field with your refresh token in the dialog with the retrieved token.

You can also use the provided Simba python script to generate a refresh token. To run this script, python 3 must be installed. You need to login with your Google account on a browser on this system.

Note:

If you use your client credentials to generate a refresh token, you cannot use it in conjunction with the default client credentials. Conversely, if you use a refresh token generated with the default client credentials, it cannot be used in conjunction with your user client credentials.

To configure authentication by retrieving a refresh token on a non-Windows machine:

1. In the `[INSTALL_DIR]/Tools` directory, run `python get_refresh_token.py` in the terminal.

For help, run the following script:

```
<python3> <install_dir>/Tools/get_refresh_token.py --help
```

2. The script opens an URL in a browser and prints out the URL in the terminal.
3. Log in with your user account and click **Allow** when you are prompted to allow the client (default client or your own client) to access your data in Google cloud with specific scopes.
4. If the request is successful, the refresh token will be printed out in the terminal. If any requests receive an error, the error is printed out in the terminal as well.

Providing a Refresh Token

If you already have your refresh token, then you can provide the token in your connection information without going through the retrieval process described above.

To configure user account authentication by providing a refresh token on Windows:

1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
2. From the **OAuth Mechanism** drop-down list, select **User Authentication**.
3. In the **Refresh Token** field, type the refresh token associated with your user account.

Providing a Key File

As an alternative to providing your refresh token directly in your connection information, you can save the token in a `.json` key file and then specify the path to the file in your connection information.

The file must define a JSON object of type `authorized_user` containing the refresh token, client ID, and client secret associated with your user account. For example, the `.json` key file must be written in the following format:

```
{
  "type": "authorized_user",
  "client_id": "[YourClientID]",
  "client_secret": "[YourClientSecret]",
  "refresh_token": "[YourRefreshToken]"
}
```

To configure user account authentication by providing a key file on Windows:

1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
2. From the **OAuth Mechanism** drop-down list, select **Service Authentication**.

Note:

Although this is a form of user authentication, the key file must be provided using the service authentication options.

3. In the **Key File Path** field, type the full path to the `.json` key file.

Using a Google Service Account

You can configure the connector to authenticate the connection with a Google service account. When you authenticate your connection this way, the connector handles authentication on behalf of the service account, so that an individual user account is not directly involved and no user input is required.

To authenticate your connection this way, you must provide a Google service account email address and the full path to a private key file for the service account. You can generate and download the private key file when you set up the service account.

Note:

- For more information about OAuth 2.0 authentication using a service account, see "Using OAuth 2.0 for Server to Server Applications" in the Google Identity Platform documentation:
<https://developers.google.com/identity/protocols/OAuth2ServiceAccount>
- For information about obtaining service account keys, see "Creating and Managing Service Account Keys" in the Google Cloud Identity & Access Management documentation:
<https://cloud.google.com/iam/docs/creating-managing-service-account-keys>.

To configure service account authentication on Windows:

1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
2. From the **OAuth Mechanism** drop-down list, select **Service Authentication**.
3. In the **Email** field, type your service account email ID.
4. In the **Key File Path** field, type the full path to the `.json` key file that is used to authenticate the service account ID.

Using an External Account

You can configure the connector to authenticate the connection with an external account (workforce identity federation), with limited support, using Azure AD and Okta identity providers.

To authenticate your connection this way, you must have workforce identity federation set up with Azure AD or Okta, and provide a configuration file in the connection string. The configuration file can be downloaded from the [Google API Console](#). For example, the following is the required format of the configuration file:

```
{
  "type": "external_account",
  "audience": "//iam.googleapis.com/locations/[LOCATION]/workforcePools/[WORKFORCE_POOL_ID]/providers/[PROVIDER_ID]",
  "subject_token_type": "urn:ietf:params:oauth:token-type:id_token",
  "token_url": "https://sts.googleapis.com/v1/token",
  "workforce_pool_user_project": "[WORKFORCE_POOL_USER_PROJECT]",
  "credential_source": {
    "file": "[PATH_TO_OIDC_CREDENTIALS]"
  }
}
```

The above properties are defined as follows:

- `audience` is the audience URI of the identity provider pool.
- `subject_token_type` is the type of token stored in the credential source.
- `token_url` is the endpoint to which a request is sent to exchange the ID token in the credential source, for a Google Cloud Platform access token.
- `workforce_pool_user_project` is the Google Cloud Platform project to which the token exchange request is executed.
- `credential_source` are the defined requirements and entities required for obtaining a subject token.

Further details are as follows:

- `subject_token_type` and `token_url` can be defaulted to the values shown in the above example, and can be selectively excluded.
- `credential_source` supports several forms, but the connector requires that the provided source is assigned to a plaintext file path, where the OIDC subject token is stored. This file must be regularly updated with a new subject token, as subject tokens expire and cannot be used to obtain access tokens. The contents of the file must be the subject token only, otherwise the exchange will fail. For

example:

```
"file": "[PATH_TO_TEXT_FILE_WITH_SUBJECT_TOKEN]"
```

Note:

For additional examples, see "Configure Workforce Identity Federation with Azure AD and Sign In Users" and "Configure Workforce Identity Federation with Okta and Sign In Users" in the Google Cloud documentation:

<https://cloud.google.com/iam/docs/workforce-sign-in-azure-ad> and

<https://cloud.google.com/iam/docs/workforce-sign-in-okta>, respectively.

To configure workforce identity federation authentication on Windows using the Key File Path option:

1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
2. From the **OAuth Mechanism** drop-down list, select **External Account Authentication**.
3. In the **Key File Path** field, type the full path of the external account configuration file.

Note:

- For more information about using external accounts, see "Workforce Identity Federation" in the Google Cloud documentation: <https://cloud.google.com/iam/docs/workforce-identity-federation>.
- When the connector is configured to use **External Account Authentication** (OAuthMechanism=4), connection properties are considered in the following precedence:
 1. KeyFile
 2. KeyFilePath (or KeyFilePath_Enc if the key file is not set)
 3. BYOID_properties
- It is recommended to set the corresponding BYOID_ property in the configuration file. These properties are intended to act as an option for customers who cannot specify .json key files to pass to the KeyFile property.

Using Application Default Credentials

You can configure the connector to authenticate the connection with Application Default Credentials. When you authenticate your connection this way, the connector parses the JSON keyfile specified by the `GOOGLE_APPLICATION_CREDENTIALS` environment variable. No other connection properties are required to use the Application Default Credentials authentication flow.

To configure Application Default Credentials authentication on Windows:

1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
2. From the **OAuth Mechanism** drop-down list, select **Application Default Credentials Authentication**.

Note:

For more information about Application Default Credentials, please refer to "How Application Default Credentials works" and "Set up Application Default Credentials" in the Google Cloud documentation:

<https://cloud.google.com/docs/authentication/application-default-credentials> and <https://cloud.google.com/docs/authentication/provide-credentials-adc>, respectively.

Configuring a Proxy Connection on Windows

If you are connecting to the data source through a proxy server, you must provide connection information for the proxy server.

To configure a proxy server connection on Windows:

1. To access proxy server options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then click **Proxy Options**.
2. Select the **Use Proxy Server** check box.
3. In the **Proxy Host** field, type the host name or IP address of the proxy server.
4. In the **Proxy Port** field, type the number of the TCP port that the proxy server uses to listen for client connections.
5. In the **Proxy Username** field, type your user name for accessing the proxy server.
6. In the **Proxy Password** field, type the password corresponding to the user name.
7. To save your settings and close the Proxy Options dialog box, click **OK**.

Note:

For proxies, the following URIs are allowed:

- `crl.pki.goog`
- `crls.pki.goog`
- `ocsp.pki.goog`

Configuring Advanced Options on Windows

You can configure advanced options to modify the behavior of the connector.

To configure advanced options on Windows:

1. To access advanced options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then click **Advanced Options**.
2. From the **Language Dialect** drop-down list, select the SQL syntax to use when executing queries:
 - To use standard SQL syntax, select **Standard SQL**.
 - Or, to use the legacy BigQuery SQL syntax, select **Legacy SQL**.
3. To allow query results that are larger than the BigQuery maximum result sizes when using Legacy SQL, select the **Allow Large Result Sets** check box.

Note:

- This option is only available if the Language Dialect drop-down list is set to Legacy SQL. Large result sets are always enabled if the Language Dialect drop-down list is set to Standard SQL.
- For more information about BigQuery maximum result sizes, see "Quotas and Limits" in the Google BigQuery documentation: https://cloud.google.com/bigquery/quotas#query_jobs.

4. To specify the dataset that stores temporary tables for large result sets, do one of the following:
 - To use the default dataset with the ID `_bqodbc_temp_tables`, select the **Use Default _bqodbc_temp_tables Large Results Dataset** check box.
 - Or, to specify a different dataset, clear the **Use Default _bqodbc_temp_tables Large Results Dataset** check box and, in the **Dataset Name For Large Result Sets** field, type the ID of the BigQuery dataset that you want to use.

Note:

- If the dataset does not exist and the data store specifies the US region, the connector creates the dataset.
- These options are only available if the connector is configured to use large result sets.

5. In the **Default temp table expiration time (ms)** field, type the length of time, in milliseconds, for which the temporary tables exist for large results datasets. The minimum value is 3600000.

Note:

This option is only available if the connector is configured to use large result sets.

6. In the **Rows Per Block** field, type the maximum number of rows to fetch for each data request.
7. To use the High-Throughput API to handle large result sets more efficiently, select the **Allow High-Throughput API for Large Results queries** check box. For more information, including prerequisites and detailed instructions, see [Configuring the High-Throughput API on Windows](#) on page 22.
8. To use a customer-managed encryption key (CMEK) when executing queries, in the **Path To CMEK** field, type the resource ID of the CMEK. For more information, see "Protecting Data with Cloud KMS Keys" in the Google BigQuery documentation: <https://cloud.google.com/bigquery/docs/customer-managed-encryption>.

Important:

- Do not specify a CMEK unless you are certain that it is the correct value to use. If you execute an INSERT statement with an incorrect CMEK, the connector returns an error or corrupts the table.
- The connector uses the specified CMEK for all queries.
- The `KMSKeyName` property is used only when the connector is configured to use the destination tables.

9. In the **Default String Column Length** field, type the maximum number of characters that can be contained in STRING columns.
10. To create a session ID from the first executed query on a connection, select the **Enable Session** check box.
 - Optionally, in the **Session Location** field, type the desired location.

11. To return data as SQL_WVARCHAR data instead of SQL_VARCHAR data, select the **Use SQL_WVARCHAR Instead Of SQL_VARCHAR** check box.

Note:

This option applies only to result set columns that the connector would normally return as SQL_VARCHAR columns. It does not convert all columns into SQL_WVARCHAR.

12. To access public projects and use them as catalogs for the connection, in the **Additional Projects** field, type a comma-separated list of project names.
13. To pass properties down to the server when inserting a job, in the **Query Properties** field, type a comma-separated list of key value pairs.
14. To save your settings and close the Advanced Options dialog box, click **OK**.

Configuring the High-Throughput API on Windows

You can configure the connector to use the High-Throughput API to handle large result sets more efficiently. For more information about the High-Throughput API, see [High-Throughput API](#) on page 69.

To configure the High-Throughput API on Windows:

1. Make sure that your Google BigQuery project has the Storage API enabled. For more information about the Storage API, see "BigQuery Storage API Overview" in the Google BigQuery documentation:
<https://cloud.google.com/bigquery/docs/reference/storage/>.
2. To access the DSN that you want to configure the High-Throughput API for, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**.
3. Choose one:
 - To verify the server using the trusted CA certificates from a specific .pem file, specify the full path to the file in the **Trusted Certificates** field and leave the **Use System Trust Store** check box cleared.
 - Or, to use the trusted CA certificates .pem file that is installed with the connector, leave the default value in the **Trusted Certificates** field, and leave the **Use System Trust Store** check box cleared.

Important:

Do not select the Use System Trust Store check box. The High-Throughput API is not compatible with the Windows Trust Store.

4. Click **Advanced Options**.
5. If you are using Legacy SQL (the **Language Dialect** drop-down list is set to **Legacy SQL**), then make sure that the **Allow Large Result Sets** check box is selected.
6. To specify the dataset that stores temporary tables for large result sets and result sets returned by the High-Throughput API, do one of the following:
 - To use the default dataset with the ID `_bqodbc_temp_tables`, select the **Use Default _bqodbc_temp_tables Large Results Dataset** check box.
 - Or, to specify a different dataset, clear the **Use Default _bqodbc_temp_tables Large Results Dataset** check box and, in the **Dataset Name For Large Result Sets** field, type the ID of the BigQuery dataset that you want to use.

Note:

- If the dataset does not exist and the data store specifies the US region, the connector creates the dataset.
- These options are only available if the connector is configured to use large result sets.

7. Optionally, if you want to use large results and query the data with the HTAPI, select the **Allow High-Throughput API for Large Results queries** check box.
8. In the **Activation Threshold for High-Throughput API** field, specify the minimum total pages required to activate reading through the High-Throughput API.
9. To save your settings and close the Advanced Options dialog box, click **OK**.

The connector now uses the BigQuery High-Throughput API instead of the REST API for requests where:

- the number of pages in the results exceeds the Activation Threshold for High-Throughput API value.
- And, if the request uses large result dataset, the Allow High-Throughput API for Large Results Dataset property is set.

Configuring Logging Options on Windows

To help troubleshoot issues, you can enable logging. In addition to functionality provided in the Simba Google BigQuery ODBC Connector, the ODBC Data Source Administrator provides tracing functionality.

⚠ Important:

Only enable logging or tracing long enough to capture an issue. Logging or tracing decreases performance and can consume a large quantity of disk space.

Configuring Connector-wide Logging Options

The settings for logging apply to every connection that uses the Simba Google BigQuery ODBC Connector, so make sure to disable the feature after you are done using it. To configure logging for the current connection, see [Configuring Logging for the Current Connection](#) on page 25.

To enable connector-wide logging on Windows:

1. To access logging options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then click **Logging Options**.
2. From the **Log Level** drop-down list, select the logging level corresponding to the amount of information that you want to include in log files:

Logging Level	Description
OFF	Disables all logging.
FATAL	Logs severe error events that lead the connector to abort.
ERROR	Logs error events that might allow the connector to continue running.
WARNING	Logs events that might result in an error if action is not taken.
INFO	Logs general information that describes the progress of the connector.
DEBUG	Logs detailed information that is useful for debugging the connector.
TRACE	Logs all connector activity.

3. In the **Log Path** field, specify the full path to the folder where you want to save log files. You can type the path into the field, or click **Browse** and then browse to select the folder.
4. In the **Max Number Files** field, type the maximum number of log files to keep.

Note:

After the maximum number of log files is reached, each time an additional file is created, the connector deletes the oldest log file.

5. In the **Max File Size** field, type the maximum size of each log file in megabytes (MB).

Note:

After the maximum file size is reached, the connector creates a new file and continues logging.

6. Click **OK**.
7. Restart your ODBC application to make sure that the new settings take effect.

The Simba Google BigQuery ODBC Connector produces the following log files at the location you specify in the Log Path field:

- A `simbabigqueryodbcdriver.log` file that logs connector activity that is not specific to a connection.
- A `simbabigqueryodbcdriver_connection_[Number].log` file for each connection made to the database, where *[Number]* is a number that identifies each log file. This file logs connector activity that is specific to the connection.

To disable connector logging on Windows:

1. Open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then click **Logging Options**.
2. From the **Log Level** drop-down list, select **LOG_OFF**.
3. Click **OK**.
4. Restart your ODBC application to make sure that the new settings take effect.

Configuring Logging for the Current Connection

You can configure logging for the current connection by setting the logging configuration properties in the DSN or in a connection string. For information about the logging configuration properties, see [Configuring Logging Options on Windows](#) on

page 23. Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

Note:

If the LogLevel configuration property is passed in via the connection string or DSN, the rest of the logging configurations are read from the connection string or DSN and not from the existing connector-wide logging configuration.

To configure logging properties in the DSN, you must modify the Windows registry. For information about the Windows registry, see the Microsoft Windows documentation.

Important:

Editing the Windows Registry incorrectly can potentially cause serious, system-wide problems that may require re-installing Windows to correct.

To add logging configurations to a DSN on Windows:

1. On the Start screen, type **regedit**, and then click the **regedit** search result.
2. Navigate to the appropriate registry key for the bitness of your connector and your machine:
 - 32-bit System DSNs: **HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\ODBC\ODBC.INI***[DSN Name]*
 - 64-bit System DSNs: **HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI***[DSN Name]*
 - 32-bit and 64-bit User DSNs: **HKEY_CURRENT_USER\SOFTWARE\ODBC\ODBC.INI***[DSN Name]*
3. For each configuration option that you want to configure for the current connection, create a value by doing the following:
 - a. If the key name value does not already exist, create it. Right-click the *[DSN Name]* and then select **New > String Value**, type the key name of the configuration option, and then press **Enter**.
 - b. Right-click the key name and then click **Modify**.

To confirm the key names for each configuration option, see [Connector Configuration Properties](#) on page 73.
 - c. In the Edit String dialog box, in the **Value Data** field, type the value for the configuration option.

4. Close the Registry Editor.
5. Restart your ODBC application to make sure that the new settings take effect.

Verifying the Connector Version Number on Windows

If you need to verify the version of the Simba Google BigQuery ODBC Connector that is installed on your Windows machine, you can find the version number in the ODBC Data Source Administrator.

To verify the connector version number on Windows:

1. From the Start menu, go to **ODBC Data Sources**.

Note:

Make sure to select the ODBC Data Source Administrator that has the same bitness as the client application that you are using to connect to BigQuery.

2. Click the **Drivers** tab and then find the Simba Google BigQuery ODBC Connector in the list of ODBC Connectors that are installed on your system. The version number is displayed in the **Version** column.

macOS Connector

macOS System Requirements

Install the connector on client machines where the application is installed. Each client machine that you install the connector on must meet the following minimum system requirements:

- One of the following macOS versions:
 - macOS 11 (Universal Binary - Intel and ARM support)
- 150MB of available disk space
- One of the following ODBC driver managers installed:
 - iODBC 3.52.9 or later
 - unixODBC 2.2.14 or later

Installing the Connector on macOS

If you did not obtain this connector from the Simba website, you might need to follow a different installation procedure. For more information, see the *Simba OEM ODBC Connectors Installation Guide*.

The Simba Google BigQuery ODBC Connector is available for macOS as a .dmg file named `SimbaODBCDriverforGoogleBigQuery.dmg`. The connector supports both 32- and 64-bit client applications.

To install the Simba Google BigQuery ODBC Connector on macOS:

1. Double-click **SimbaODBC DriverforGoogleBigQuery.dmg** to mount the disk image.
2. Double-click **SimbaODBCDriverforGoogleBigQuery.pkg** to run the installer.
3. In the installer, click **Continue**.
4. On the Software License Agreement screen, click **Continue**, and when the prompt appears, click **Agree** if you agree to the terms of the License Agreement.
5. Optionally, to change the installation location, click **Change Install Location**, then select the desired location, and then click **Continue**.

Note:

By default, the files are installed in the `/Library/simba/googlebigqueryodbc` directory.

6. To accept the installation location and begin the installation, click **Install**.
7. When the installation completes, click **Close**.
8. If you received a license file through email, then copy the license file into the `/lib` subfolder in the installation directory. You must have root privileges when changing the contents of this folder.

For example, if you installed the connectors to the default location, you would copy the license file into the `/Library/simba/googlebigqueryodbc/lib` folder.

Next, configure the environment variables on your machine to make sure that the ODBC Driver manager can work with the . For more information, see [Configuring the ODBC Driver Manager on Non-Windows Machines](#) on page 34.

Verifying the Connector Version Number on macOS

If you need to verify the version of the Simba Google BigQuery ODBC Connector that is installed on your macOS machine, you can query the version number through the Terminal.

To verify the connector version number on macOS:

- At the Terminal, run the following command:

```
pkgutil --info com.simba.googlebigqueryodbc
```

The command returns information about the Simba Google BigQuery ODBC Connector that is installed on your machine, including the version number.

Linux Connector

The Linux connector is available as an RPM file and as a tarball package.

Linux System Requirements

Install the connector on client machines where the application is installed. Each client machine that you install the connector on must meet the following minimum system requirements:

- One of the following distributions:
 - Red Hat® Enterprise Linux® (RHEL) 7, 8, or 9
 - CentOS 7
 - SUSE Linux Enterprise Server (SLES) 12 or 15
 - Debian 10 or 11
 - Ubuntu 20.04 or 22.04
- 150MB of available disk space
- One of the following ODBC driver managers installed:
 - iODBC 3.52.9 or later
 - unixODBC 2.2.14 or later
- glibc 2.17 or later

To install the connector, you must have root access on the machine.

Installing the Connector Using the RPM File

If you did not obtain this connector from the Simba website, you might need to follow a different installation procedure. For more information, see the *Simba OEM ODBC connectors Installation Guide*.

On 64-bit editions of Linux, you can execute both 32- and 64-bit applications. However, 64-bit applications must use 64-bit connectors, and 32-bit applications must use 32-bit connectors. Make sure that you use a connector whose bitness matches the bitness of the client application:

- `simbagooglebigquery-[Version]-[Release].i686.rpm` for the 32-bit connector
- `simbagooglebigquery-[Version]-[Release].x86_64.rpm` for the 64-bit connector

The placeholders in the file names are defined as follows:

- *[Version]* is the version number of the connector.
- *[Release]* is the release number for this version of the connector.

You can install both the 32-bit and 64-bit versions of the connector on the same machine.

To install the Simba Google BigQuery ODBC Connector using the RPM File:

1. Log in as the root user.
2. Navigate to the folder containing the RPM package for the connector.
3. Depending on the Linux distribution that you are using, run one of the following commands from the command line, where *[RPMFileName]* is the file name of the RPM package:

- If you are using Red Hat Enterprise Linux or CentOS, run the following command:

```
yum --nogpgcheck localinstall [RPMFileName]
```

- Or, if you are using SUSE Linux Enterprise Server, run the following command:

```
zypper install [RPMFileName]
```

The Simba Google BigQuery ODBC Connector files are installed in the `/opt/simba/googlebigqueryodbc` directory.

4. If you received a license file through email, then copy the license file into the `/opt/simba/googlebigqueryodbc/lib/32` or `/opt/simba/googlebigqueryodbc/lib/64` folder, depending on the version of the connector that you installed.

Next, configure the environment variables on your machine to make sure that the ODBC Driver manager can work with the connector. For more information, see [Configuring the ODBC Driver Manager on Non-Windows Machines](#) on page 34.

Installing the Connector Using the Tarball Package

If you did not obtain this connector from the Simba website, you might need to follow a different installation procedure. For more information, see the *Simba OEM ODBC Connectors Installation Guide*.

The Simba Google BigQuery ODBC Connector is available as a tarball package named `SimbaODBCDriverforGoogleBigQuery_[Version].[Release]-Linux.tar.gz`, where *[Version]* is the version number of the connector and *[Release]* is the release number for this version of the connector. The package contains both the 32-bit and 64-bit versions of the connector.

On 64-bit editions of Linux, you can execute both 32- and 64-bit applications. However, 64-bit applications must use 64-bit connectors, and 32-bit applications must use 32-bit connectors. Make sure that you use a connector whose bitness matches the bitness of the client application. You can install both versions of the connector on the same machine.

To install the connector using the tarball package:

1. Create the directory of where you want to install the connector, if it does not already exist.
2. Extract the main tarball file to a convenient temporary location.
3. Extract the inner tarball file, corresponding to the version of the connector you want to install (32-bit or 64-bit), to a convenient temporary location.
4. Navigate to the subfolder of the extracted inner tarball file, as done in the previous step, and then copy all the files and folders to the installation directory.
5. Navigate to the temporary location of the extracted main tarball file done in step 2, and then copy the `Tools` folder to the installation directory.
6. Navigate to the temporary location of the extracted main tarball file in step 2, and then copy the `GoogleBigQueryODBC.did` file to the `/lib` subfolder in the installation directory.
7. The Simba Google BigQuery ODBC Connector path is now `[INSTALLDIR]/lib/[FileName].so`. You can make required changes in the `.ini` files to correct path of connector .

Next, configure the environment variables on your machine to make sure that the ODBC Driver manager can work with the connector. For more information, see [Configuring the ODBC Driver Manager on Non-Windows Machines](#) on page 34.

Verifying the Connector Version Number on Linux

If you need to verify the version of the Simba Google BigQuery ODBC Connector that is installed on your Linux machine, you can query the version number through the command-line interface if the connector was installed using an RPM file. Alternatively, you can search the connector's binary file for version number information.

To verify the connector version number on Linux using the command-line interface:

- Depending on your package manager, at the command prompt, run one of the following commands:

- `yum list 'Simba*'] grep SimbaODBCDriverforGoogleBigQuery`
- `rpm -qa | grep SimbaODBCDriverforGoogleBigQuery`

The command returns information about the Simba Google BigQuery ODBC Connector that is installed on your machine, including the version number.

To verify the connector version number on Linux using the binary file:

1. Navigate to the `/lib` subfolder in your connector installation directory. By default, the path to this directory is:
`/opt/simba/googlebigqueryodbc/lib`.
2. Open the connector's `.so` binary file in a text editor, and search for the text `$driver_version_sb$:.` . The connector's version number is listed after this text.

Configuring the ODBC Driver Manager on Non-Windows Machines

To make sure that the ODBC Driver manager on your machine is configured to work with the Simba Google BigQuery ODBC Connector, do the following:

- Set the library path environment variable to make sure that your machine uses the correct ODBC Driver manager. For more information, see [Specifying ODBC Driver Managers on Non-Windows Machines](#) on page 34.
- If the connector configuration files are not stored in the default locations expected by the ODBC Driver manager, then set environment variables to make sure that the driver manager locates and uses those files. For more information, see [Specifying the Locations of the Connector Configuration Files](#) on page 35.

After configuring the ODBC Driver manager, you can configure a connection and access your data store through the connector.

Specifying ODBC Driver Managers on Non-Windows Machines

You need to make sure that your machine uses the correct ODBC Driver manager to load the connector. To do this, set the library path environment variable.

macOS

If you are using a macOS machine, then set the `DYLD_LIBRARY_PATH` environment variable to include the paths to the ODBC driver manager libraries. For example, if the libraries are installed in `/usr/local/lib`, then run the following command to set `DYLD_LIBRARY_PATH` for the current user session:

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/usr/local/lib
```

For information about setting an environment variable permanently, refer to the macOS shell documentation.

Linux

If you are using a Linux machine, then set the `LD_LIBRARY_PATH` environment variable to include the paths to the ODBC driver manager libraries. For example, if the libraries are installed in `/usr/local/lib`, then run the following command to set `LD_LIBRARY_PATH` for the current user session:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/usr/local/lib
```

For information about setting an environment variable permanently, refer to the Linux shell documentation.

Specifying the Locations of the Connector Configuration Files

By default, ODBC Driver managers are configured to use hidden versions of the `odbc.ini` and `odbcinst.ini` configuration files (named `.odbc.ini` and `.odbcinst.ini`) located in the home directory, as well as the `simba.googlebigqueryodbc.ini` file in the `lib` subfolder of the connector installation directory. If you store these configuration files elsewhere, then you must set the environment variables described below so that the driver manager can locate the files.

If you are using iODBC, do the following:

- Set `ODBCINI` to the full path and file name of the `odbc.ini` file.
- Set `ODBCINSTINI` to the full path and file name of the `odbcinst.ini` file.
- Set `SIMBAGOOGLBIGQUERYODBCINI` to the full path and file name of the `simba.googlebigqueryodbc.ini` file.

If you are using unixODBC, do the following:

- Set `ODBCINI` to the full path and file name of the `odbc.ini` file.
- Set `ODBCSYSINI` to the full path of the directory that contains the `odbcinst.ini` file.
- Set `SIMBAGOOGLBIGQUERYODBCINI` to the full path and file name of the `simba.googlebigqueryodbc.ini` file.

For example, if your `odbc.ini` and `odbcinst.ini` files are located in `/usr/local/odbc` and your `simba.googlebigqueryodbc.ini` file is located in `/etc`, then set the environment variables as follows:

For iODBC:

```
export ODBCINI=/usr/local/odbc/odbc.ini
export ODBCINSTINI=/usr/local/odbc/odbcinst.ini
export
SIMBAGOOGLBIGQUERYODBCINI=/etc/simba.googlebigqueryodbc.ini
```

For unixODBC:

```
export ODBCINI=/usr/local/odbc/odbc.ini
export ODBCSYSINI=/usr/local/odbc
export
SIMBAGOOGLBIGQUERYODBCINI=/etc/simba.googlebigqueryodbc.ini
```

To locate the `simba.googlebigqueryodbc.ini` file, the connector uses the following search order:

1. If the `SIMBAGOOGLEBIGQUERYODBCINI` environment variable is defined, then the connector searches for the file specified by the environment variable.
2. The connector searches the directory that contains the connector library files for a file named `simba.googlebigqueryodbc.ini`.
3. The connector searches the current working directory of the application for a file named `simba.googlebigqueryodbc.ini`.
4. The connector searches the home directory for a hidden file named `.simba.googlebigqueryodbc.ini` (prefixed with a period).
5. The connector searches the `/etc` directory for a file named `simba.googlebigqueryodbc.ini`.

Configuring ODBC Connections on a Non-Windows Machine

The following sections describe how to configure ODBC connections when using the Simba Google BigQuery ODBC Connector on non-Windows platforms:

- [Creating a Data Source Name on a Non-Windows Machine on page 37](#)
- [Setting Connector-Wide Configuration Options on a Non-Windows Machine on page 40](#)
- [Configuring a DSN-less Connection on a Non-Windows Machine on page 40](#)
- [Configuring Authentication on a Non-Windows Machine on page 43](#)
- [Configuring the High-Throughput API on a Non-Windows Machine on page 51](#)
- [Configuring Logging Options on a Non-Windows Machine on page 53](#)
- [Testing the Connection on a Non-Windows Machine on page 54](#)

Creating a Data Source Name on a Non-Windows Machine

When connecting to your data store using a DSN, you only need to configure the `odbc.ini` file. Set the properties in the `odbc.ini` file to create a DSN that specifies the connection information for your data store. For information about configuring a DSN-less connection instead, see [Configuring a DSN-less Connection on a Non-Windows Machine on page 40](#).

If your machine is already configured to use an existing `odbc.ini` file, then update that file by adding the settings described below. Otherwise, copy the `odbc.ini` file from the `Setup` subfolder in the connector installation directory to the home directory, and then update the file as described below.

To create a Data Source Name on a non-Windows machine:

1. In a text editor, open the `odbc.ini` configuration file.

Note:

If you are using a hidden copy of the `odbc.ini` file, you can remove the period (.) from the start of the file name to make the file visible while you are editing it.

2. In the `[ODBC Data Sources]` section, add a new entry by typing a name for the DSN, an equal sign (=), and then the name of the connector.

For example, on a macOS machine:

```
[ODBC Data Sources]
Sample DSN=Simba Google BigQuery ODBC Connector
```

As another example, for a 32-bit connector on a Linux machine:

```
[ODBC Data Sources]
Sample DSN=Simba Google BigQuery ODBC Connector 32-bit
```

3. Create a section that has the same name as your DSN, and then specify configuration options as key-value pairs in the section:
 - a. Set the `Driver` property to the full path of the connector library file that matches the bitness of the application.

For example, on a macOS machine:

```
Driver=/Library/
simba/googlebigqueryodbc/lib/libgooglebigqueryodbc_
sb64-universal.dylib
```

As another example, for a 32-bit connector on a Linux machine:

```
Driver=/opt/
simba
/googlebigqueryodbc/lib/32/libgooglebigqueryodbc_
sb32.so
```

- b. Set the `Catalog` property to the name of your BigQuery project. This project is the default project that the Simba Google BigQuery ODBC Connector queries against, and also the project that is billed for queries that are run using this DSN.

For example:

```
Catalog=testdata
```

- c. Configure authentication using a Google user account or a Google service account. For more information, see [Configuring Authentication on a Non-Windows Machine](#) on page 43.
 - d. Optionally, to use trusted CA certificates from a `.pem` file other than the default file installed with the connector, set the `TrustedCerts` property to the full path of the file.
 - e. Optionally, to allow the connector to access Google Drive so that it can support federated tables that combine BigQuery data with data from Google Drive, set the `RequestGoogleDriveScope` property to 1.

- f. Optionally, set additional key-value pairs as needed to specify other optional connection settings. For detailed information about all the configuration options supported by the Simba Google BigQuery ODBC Connector, see [Connector Configuration Properties](#) on page 73.
4. Save the `odbc.ini` configuration file.

Note:

If you are storing this file in its default location in the home directory, then prefix the file name with a period (`.`) so that the file becomes hidden. If you are storing this file in another location, then save it as a non-hidden file (without the prefix), and make sure that the `ODBCINI` environment variable specifies the location. For more information, see [Specifying the Locations of the Connector Configuration Files](#) on page 35.

For example, the following is an `odbc.ini` configuration file for macOS containing a DSN that connects to Google BigQuery using a refresh token obtained from a user account:

```
[ODBC Data Sources]
Sample DSN=Simba Google BigQuery ODBC Connector
[Sample DSN]
Driver=/Library/
simba/googlebigqueryodbc/lib/libgooglebigqueryodbc_sb64-
universal.dylib
Catalog=testdata
OAuthMechanism=1
RefreshToken=CH01pcNn/qFcYwUlJpkF_yyufYrqj404g7cdXvGgs-zT6
```

As another example, the following is an `odbc.ini` configuration file for a 32-bit connector on a Linux machine, containing a DSN that connects to Google BigQuery using a refresh token obtained from a user account:

```
[ODBC Data Sources]
Sample DSN=Simba Google BigQuery ODBC Connector 32-bit
[Sample DSN]
Driver=/opt/
simba/googlebigqueryodbc/lib/32/libgooglebigqueryodbc_sb32.so
Catalog=testdata
OAuthMechanism=1
RefreshToken=CH01pcNn/qFcYwUlJpkF_yyufYrqj404g7cdXvGgs-zT6
```

You can now use the DSN in an application to connect to the data store.

Setting Connector-Wide Configuration Options on a Non-Windows Machine

When you specify connection settings in a DSN or connection string, those settings apply only when you connect to BigQuery using that particular DSN or string. As an alternative, you can specify certain settings that apply to every connection that uses the Simba Google BigQuery ODBC Connector by configuring them in the `simba.googlebigqueryodbc.ini` file.

Note:

Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To set connector-wide configuration options on a non-Windows machine:

1. In a text editor, open the `simba.googlebigqueryodbc.ini` configuration file.
2. In the `[Driver]` section, specify configuration properties as key-value pairs. Start a new line for each key-value pair.

For example, to specify a proxy server and to log information from the libcurl library, type the following:

```
Proxy=http://proxy.mycompany.ca:1066  
CURLVerboseMode=true
```

For detailed information about the configuration options supported by the connector at the connector-wide level, see below.

3. Save the `simba.googlebigqueryodbc.ini` configuration file.
4. Restart your ODBC application to make sure that the new settings take effect.

The `MaxThreads` property must be configured in the `simba.googlebigqueryodbc.ini` file, or as a Windows Registry key value on Windows. For more information see [MaxThreads](#) on page 99.

Configuring a DSN-less Connection on a Non-Windows Machine

To connect to your data store through a DSN-less connection, you need to define the connector in the `odbcinst.ini` file and then provide a DSN-less connection string in your application.

If your machine is already configured to use an existing `odbcinst.ini` file, then update that file by adding the settings described below. Otherwise, copy the `odbcinst.ini` file from the `Setup` subfolder in the connector installation directory to the home directory, and then update the file as described below.

To define a connector on a non-Windows machine:

1. In a text editor, open the `odbcinst.ini` configuration file.

Note:

If you are using a hidden copy of the `odbcinst.ini` file, you can remove the period (.) from the start of the file name to make the file visible while you are editing it.

2. In the `[ODBC Drivers]` section, add a new entry by typing a name for the connector, an equal sign (=), and then `Installed`.

For example:

```
[ODBC Drivers]
Simba BigQuery ODBC Driver=Installed
```

3. Create a section that has the same name as the connector (as specified in the previous step), and then specify the following configuration options as key-value pairs in the section:
 - a. Set the `Driver` property to the full path of the connector library file that matches the bitness of the application.

For example, on a macOS machine:

```
Driver=/Library/
simba/googlebigqueryodbc/lib/libgooglebigqueryodbc_
sbu.dylib
```

As another example, for a 32-bit connector on a Linux machine:

```
Driver=/opt/
simba
/googlebigqueryodbc/lib/32/libgooglebigqueryodbc_
sb32.so
```

- b. Optionally, set the `Description` property to a description of the connector.

For example:

```
Description=Simba Google BigQuery ODBC Connector
```

4. Save the `odbcinst.ini` configuration file.

Note:

If you are storing this file in its default location in the home directory, then prefix the file name with a period (.) so that the file becomes hidden. If you are storing this file in another location, then save it as a non-hidden file (without the prefix), and make sure that the `ODBCINSTINI` or `ODBCSYSINI` environment variable specifies the location. For more information, see [Specifying the Locations of the Connector Configuration Files](#) on page 35.

For example, the following is an `odbcinst.ini` configuration file for macOS:

```
[ODBC Drivers]
Simba Google BigQuery ODBC Connector=Installed
[Simba BigQuery ODBC Connector]
Description= Simba Google  BigQuery ODBC Connector
Driver=/Library/
simba/googlebigqueryodbc/lib/libgooglebigqueryodbc_
sbu64.dylib
```

As another example, the following is an `odbcinst.ini` configuration file for both the 32- and 64-bit connectors on Linux:

```
[ODBC Drivers]
Simba Google BigQuery ODBC Connector 32-bit=Installed
Simba Google BigQuery ODBC Connector 64-bit=Installed
[Simba Google BigQuery ODBC Connector 32-bit]
Description=Simba Google  BigQuery ODBC Connector(32 bit)
Driver=/opt/
simba/googlebigqueryodbc/lib/32/libgooglebigqueryodbc_sb32.so
[Simba Google BigQuery ODBC Connector 64-bit]
Description=Simba Google  BigQuery ODBC Connector(64 bit)
Driver=/opt/
simba/googlebigqueryodbc/lib/64/libgooglebigqueryodbc_sb64.so
```

You can now connect to your data store by providing your application with a connection string where the `Driver` property is set to the connector name specified in

the `odbcinst.ini` file, and all the other necessary connection properties are also set. For more information, see "DSN-less Connection String Examples" in [Using a Connection String](#) on page 57.

For instructions about configuring specific connection features, see the following:

- [Configuring Authentication on a Non-Windows Machine](#) on page 43
- [Configuring the High-Throughput API on a Non-Windows Machine](#) on page 51

For detailed information about all the connection properties that the connector supports, see [Connector Configuration Properties](#) on page 73.

Configuring Authentication on a Non-Windows Machine

The Simba Google BigQuery ODBC Connector uses the OAuth 2.0 protocol for authentication and authorization. It authenticates your connection through Google OAuth APIs. You can configure the connector to provide your credentials and authenticate the connection to the database using one of the following methods:

- [Using a Google User Account](#) on page 43
- [Using a Google Service Account](#) on page 46
- [Using an External Account](#) on page 47
- [Using an Application Default Credentials](#) on page 51

Using a Google User Account

You can configure the connector to authenticate the connection with a Google user account. This authentication method uses the OAuth 2.0 access and refresh tokens associated with the user account as the credentials.

The access token is transmitted with every API call that the connector makes, and it is required for accessing BigQuery data stores. However, the access token expires after a certain amount of time and must be renewed using the refresh token. If the refresh token is stored in the DSN, the connector automatically uses it to renew access tokens when they expire.

Note:

For more information about OAuth 2.0, see "Using OAuth 2.0 to Access Google APIs" in the Google Identity Platform documentation:

<https://developers.google.com/identity/protocols/OAuth2>.

At minimum, you need to provide the OAuth 2.0 refresh token associated with your account. The connector retrieves and uses an access token based on your specified refresh token.

- If you do not have your refresh token, see [Retrieving a Refresh Token](#) on page 44.
- If you have your refresh token, see [Providing a Refresh Token](#) on page 45.
- If you want to provide a `.json` key file that contains your credentials instead of providing your refresh token directly in your connection information, see [Providing a Key File](#) on page 46.

Retrieving a Refresh Token

When you authenticate your connection this way, the authentication process provides a temporary authorization code that you can exchange for an access token and a refresh token.

You can use the provided Simba python script to generate a refresh token. To run this script, python 3 must be installed. You need to login with your Google account on a browser on this system.

Note:

If you use your client credentials to generate a refresh token, you cannot use it in conjunction with the default client credentials. Conversely, if you use a refresh token generated with the default client credentials, it cannot be used in conjunction with your user client credentials.

To configure authentication by retrieving a refresh token on a non-Windows machine:

1. In the `[INSTALL_DIR]/Tools` directory, run `python get_refresh_token.py` in the terminal.

For help, run the following script:

```
<python3> <install_dir>/Tools/get_refresh_token.py --help
```

2. The script opens an URL in a browser and prints out the URL in the terminal.
3. Log in with your user account and click **Allow** when you are prompted to allow the client (default client or your own client) to access your data in Google cloud with specific scopes.
4. If the request is successful, the refresh token will be printed out in the terminal. If any requests receive an error, the error is printed out in the terminal as well.

Now that you have a refresh token, see [Providing a Refresh Token](#) on page 45.

To configure user account authentication by retrieving a refresh token on a non-Windows machine:

1. Obtain a refresh token based on your user account:
 - a. In a web browser, navigate to the Google OAuth 2.0 Playground: <https://developers.google.com/oauthplayground/>.
 - b. In the side panel, expand **BigQuery API v2** and select the appropriate scope for the permissions that you need.

Note:

For information about the permissions associated with each scope, see "OAuth 2.0 Scopes for Google APIs" in the Google Identity Platform documentation:

<https://developers.google.com/identity/protocols/googlescopes>.

- c. Click **Authorize APIs**.
 - d. Sign in to your user account.
 - e. When you are prompted to allow Google OAuth 2.0 Playground to view and manage your data in Google BigQuery, click **Allow**.

The authentication process returns you to the Google OAuth 2.0 Playground, and automatically populates the Authorization Code field with an authorization code.

- f. Click **Exchange Authorization Code for Tokens**.

The Refresh Token and Access Token fields are populated with the appropriate token values.

2. In your DSN or connection string, set the `OAuthMechanism` property to 1.
3. Set the `RefreshToken` property to the refresh token that you obtained from Google.
4. Set the `ClientId` property to your BigQuery client ID.
5. Set the `ClientSecret` property to the corresponding client secret.

Providing a Refresh Token

If you already have your refresh token, then you can provide the token in your connection information without going through the retrieval process described above.

To configure user account authentication by providing a refresh token on a non-Windows machine:

1. Set the `OAuthMechanism` property to 1.
2. Set the `RefreshToken` property to the refresh token associated with your user account.

Providing a Key File

As an alternative to providing your refresh token directly in your connection information, you can save the token in a `.json` key file and then specify the path to the file in your connection information.

The file must define a JSON object of type `authorized_user` containing the refresh token, client ID, and client secret associated with your user account. For example, the `.json` key file must be written in the following format:

```
{
  "type": "authorized_user",
  "client_id": "[YourClientID]",
  "client_secret": "[YourClientSecret]",
  "refresh_token": "[YourRefreshToken]"
}
```

To configure user account authentication by providing a key file on a non-Windows machine:

1. Set the `OAuthMechanism` property to 0.

Note:

Although this is a form of user authentication, the connector must be configured to use the service authentication mechanism (`OAuthMechanism=0`) in order to detect and use the key file.

2. Set the `KeyFilePath` or `KeyFile` property to the full path to the `.json` key file. Alternatively, set the `KeyFile` property to the plain text JSON object.

Using a Google Service Account

You can configure the connector to authenticate the connection with a Google service account. When you authenticate your connection this way, the connector handles authentication on behalf of the service account, so that an individual user account is not directly involved and no user input is required.

To authenticate your connection this way, you must provide the full path to a private key file for the service account. You can also provide the Google service account email address. You can generate and download the private key file when you set up the service account.

Note:

- For more information about OAuth 2.0 authentication using a service account, see "Using OAuth 2.0 for Server to Server Applications" in the Google Identity Platform documentation:
<https://developers.google.com/identity/protocols/OAuth2ServiceAccount>
- For information about obtaining service account keys, see "Creating and Managing Service Account Keys" in the Google Cloud Identity & Access Management documentation:
<https://cloud.google.com/iam/docs/creating-managing-service-account-keys>.

To configure service account authentication on a non-Windows machine:

1. Set the `OAuthMechanism` property to 0.
2. Set the `Email` property to your service account email ID.
3. Set the `KeyFilePath` or `KeyFile` property to the full path to the `.json` key file that is used to authenticate the service account ID. Alternatively, set the `KeyFile` property to the plain text JSON object.

Using an External Account

You can configure the connector to authenticate the connection with an external account (workforce identity federation), with limited support, using Azure AD and Okta identity providers.

To authenticate your connection this way, you must have workforce identity federation set up with Azure AD or Okta, and provide a configuration file in the connection string. The configuration file can be downloaded from the [Google API Console](#). For example, the following is the required format of the configuration file:

```
{  
  
  "type": "external_account",
```

```
"audience": "//iam.googleapis.com/locations/  
[LOCATION]/workforcePools/[WORKFORCE_POOL_  
ID]/providers/[PROVIDER_ID]",  
  
"subject_token_type": "urn:ietf:params:oauth:token-  
type:id_token",  
  
"token_url": "https://sts.googleapis.com/v1/token",  
  
"workforce_pool_user_project": "[WORKFORCE_POOL_USER_  
PROJECT]",  
  
"credential_source": {  
    "file": "[PATH_TO_OIDC_CREDENTIALS]"  
}  
}
```

The above properties are defined as follows:

- `audience` is the audience URI of the identity provider pool.
- `subject_token_type` is the type of token stored in the credential source.
- `token_url` is the endpoint to which a request is sent to exchange the ID token in the credential source, for a Google Cloud Platform access token.
- `workforce_pool_user_project` is the Google Cloud Platform project to which the token exchange request is executed.
- `credential_source` are the defined requirements and entities required for obtaining a subject token.

Further details are as follows:

- `subject_token_type` and `token_url` can be defaulted to the values shown in the above example, and can be selectively excluded.
- `credential_source` supports several forms, but the connector requires that the provided source is assigned to a plaintext file path, where the OIDC subject token is stored. This file must be regularly updated with a new subject token, as subject tokens expire and cannot be used to obtain access tokens. The contents of the file must be the subject token only, otherwise the exchange will fail. For example:

```
"file": "[PATH_TO_TEXT_FILE_WITH_SUBJECT_TOKEN]"
```

Note:

For additional examples, see "Configure Workforce Identity Federation with Azure AD and Sign In Users" and "Configure Workforce Identity Federation with Okta and Sign In Users" in the Google Cloud documentation: <https://cloud.google.com/iam/docs/workforce-sign-in-azure-ad> and <https://cloud.google.com/iam/docs/workforce-sign-in-okta>, respectively.

Configure Workforce Identity Federation Authentication on a Non-Windows Machine Using the KeyFilePath Property

1. Set the `OAuthMechanism` property to 4.
2. Set the `KeyFilePath` property to the full path of the external account configuration file. For example:

```
Driver=Simba ODBC Driver for Google
BigQuery;...;OAuthMechanism=4;KeyFilePath=/tmp/path/to/oidc_configuration_file.json
```

Configure Workforce Identity Federation Authentication on a Non-Windows Machine Using the KeyFile Property

1. Set the `OAuthMechanism` property to 4.
2. Set the `KeyFile` property to either the full path of the external account configuration file, or a raw JSON object containing the configuration file contents. For example:

Using a file path:

```
Driver=Simba ODBC Driver for Google
BigQuery;...;OAuthMechanism=4;KeyFile=/tmp/path/to/oidc_configuration_file.json
```

Using a raw JSON object:

```
Driver=Simba ODBC Driver for Google
BigQuery;...;OAuthMechanism=4;KeyFile={"audience":
"//iam.googleapis.com/locations/
[LOCATION]/workforcePools/[POOL_ID]/providers/[PROVIDER_
ID]","workforce_pool_user_project": "[PROJECT_
ID]","credential_source": {"file": "[PATH_TO_SUBJECT_
TOKEN_FILE]"}}}}
```

Configure Workforce Identity Federation Authentication on a Non-Windows Machine Using BYOID_ Properties

1. Set the `OAuthMechanism` property to 4.
2. Set the appropriate `BYOID_` property to reconstruct the configuration file internally. The following table lists the available properties and their default values:

Property Name	SQL Default Value
<code>BYOID_AudienceUri</code>	None
<code>BYOID_CredentialSource</code>	None
<code>BYOID_PoolUserProject</code>	None
<code>BYOID_SubjectTokenType</code>	<code>urn:ietf:params:oauth:token-type:id_token</code>
<code>BYOID_TokenUri</code>	<code>https://sts.googleapis.com/v1/token</code>

Each of the above properties are strings that represent a field present in the configuration file, with the exception of `BYOID_CredentialSource`, which is a string with a JSON object. For example:

```
Driver=Simba ODBC Driver for Google BigQuery;...;BYOID_AudienceUri=//iam.googleapis.com/locations/global/workforcePools/testpool-1/providers/okta-provider-1;BYOID_PoolUserProject=898755234664;BYOID_CredentialSource={{"file": "Tests/OAuth/okta_subject_token.txt"}}
```

The above example shows the minimum properties required in the connection string. The `subject_token_type` and `token_url` properties are absent, to demonstrate that the connector will use the default values. If the corresponding `BYOID_` property (`BYOID_SubjectTokenType` or `BYOID_TokenUri`) is set, the connector will use these properties.

For more information about these properties, see [Configuration Options Having Only Key Names](#) on page 91.

Note:

- For more information about using external accounts, see "Workforce Identity Federation" in the Google Cloud documentation: <https://cloud.google.com/iam/docs/workforce-identity-federation>.
- When the connector is configured to use External Account Authentication (`OAuthMechanism=4`), connection properties are considered in the following precedence:
 1. `KeyFile`
 2. `KeyFilePath` (or `KeyFilePath_Enc` if the key file is not set)
 3. `BYOID_` properties
- It is recommended to set the corresponding `BYOID_` property in the configuration file. These properties are intended to act as an option for customers who cannot specify `.json` key files to pass to the `KeyFile` property.

Using Application Default Credentials

You can configure the connector to authenticate the connection with Application Default Credentials. When you authenticate your connection this way, the connector parses the JSON keyfile specified by the `GOOGLE_APPLICATION_CREDENTIALS` environment variable. No other connection properties are required to use the Application Default Credentials authentication flow.

To configure Application Default Credentials authentication on a non-Windows machine:

- Set the `OAuthMechanism` property to 3.

Note:

For more information about Application Default Credentials, please refer to "How Application Default Credentials works" and "Set up Application Default Credentials" in the Google Cloud documentation: <https://cloud.google.com/docs/authentication/application-default-credentials> and <https://cloud.google.com/docs/authentication/provide-credentials-adc>, respectively.

Configuring the High-Throughput API on a Non-Windows Machine

You can configure the connector to use the High-Throughput API to handle large result sets more efficiently. For more information about the High-Throughput API, see [High-](#)

[Throughput API](#) on page 69.

To configure the High-Throughput API on a non-Windows machine:

1. Make sure that your Google BigQuery project has the Storage API enabled. For more information about the Storage API, see "BigQuery Storage API Overview" in the Google BigQuery documentation:
<https://cloud.google.com/bigquery/docs/reference/storage/>.

Note:

On Linux, if the application running the connector has been built with an RPATH, then you must either include the connector directory in that RPATH, or adjust your LD_LIBRARY_PATH to include the connector directory.

2. In the `odbc.ini` file, if you are using Legacy SQL (the `SQLDialect` property is set to 0), then set the `AllowLargeResults` property to 1.
3. To specify the dataset that stores temporary tables for large result sets and result sets returned by the High-Throughput API, do one of the following:
 - To use the default dataset with the `ID_bqodbc_temp_tables`, set the `UseDefaultLargeResultsDataset` property to 1.
 - Or, to specify a different dataset, set the `UseDefaultLargeResultsDataset` property to 0 and set the `LargeResultsDataSetId` property to the ID of the BigQuery dataset that you want to use.

Note:

If the dataset does not exist and the data store specifies the US region, the connector creates the dataset.

4. Optionally, if you want to use large results and query the data with the HTAPI, set the `AllowHtapiForLargeResults` property to 1.
5. Set the `HTAPI_ActivationThreshold` property to the minimum total pages required to activate reading through the High-Throughput API.

The connector now uses the BigQuery High-Throughput API instead of the REST API for requests where:

- the number of pages in the results exceeds the `HTAPI_ActivationThreshold` value.

- And, if the request uses large result dataset, the `AllowHtapiForLargeResults` property is set.

Configuring Logging Options on a Non-Windows Machine

To help troubleshoot issues, you can enable logging in the connector.

Important:

Only enable logging long enough to capture an issue. Logging decreases performance and can consume a large quantity of disk space.

You can set the connection properties described below in a connection string, in a DSN (in the `odbc.ini` file), or as a connector-wide setting (in the `simba.googlebigqueryodbc.ini` file). Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To enable logging on a non-Windows machine:

1. To specify the level of information to include in log files, set the `LogLevel` property to one of the following numbers:

LogLevel Value	Description
0	Disables all logging.
1	Logs severe error events that lead the connector to abort.
2	Logs error events that might allow the connector to continue running.
3	Logs events that might result in an error if action is not taken.
4	Logs general information that describes the progress of the connector.
5	Logs detailed information that is useful for debugging the connector.

LogLevel Value	Description
6	Logs all connector activity.

2. Set the `LogPath` key to the full path to the folder where you want to save log files.
3. Set the `LogFileCount` key to the maximum number of log files to keep.

Note:

After the maximum number of log files is reached, each time an additional file is created, the connector deletes the oldest log file.

4. Set the `LogFileSize` key to the maximum size of each log file in bytes.

Note:

After the maximum file size is reached, the connector creates a new file and continues logging.

5. Save the `simba.googlebigqueryodbc.ini` configuration file.
6. Restart your ODBC application to make sure that the new settings take effect.

The Simba Google BigQuery ODBC Connector produces the following log files at the location you specify using the `LogPath` key:

- A `simbabigqueryodbcdriver.log` file that logs connector activity that is not specific to a connection.
- A `simbabigqueryodbcdriver_connection_[Number].log` file for each connection made to the database, where `[Number]` is a number that identifies each log file. This file logs connector activity that is specific to the connection.

To disable logging on a non-Windows machine:

1. Set the `LogLevel` key to 0.
2. Save the `simba.googlebigqueryodbc.ini` configuration file.
3. Restart your ODBC application to make sure that the new settings take effect.

Testing the Connection on a Non-Windows Machine

To test the connection, you can use an ODBC-enabled client application. For a basic connection test, you can also use the test utilities that are packaged with your driver manager installation. For example, the iODBC driver manager includes simple utilities

called `iodbctest` and `iodbctestw`. Similarly, the `unixODBC` driver manager includes simple utilities called `isql` and `iusql`.

Using the iODBC Driver Manager

You can use the `iodbctest` and `iodbctestw` utilities to establish a test connection with your connector. Use `iodbctest` to test how your connector works with an ANSI application, or use `iodbctestw` to test how your connector works with a Unicode application.

Note:

There are 32-bit and 64-bit installations of the iODBC driver manager available. If you have only one or the other installed, then the appropriate version of `iodbctest` (or `iodbctestw`) is available. However, if you have both 32- and 64-bit versions installed, then you need to make sure that you are running the version from the correct installation directory.

For more information about using the iODBC driver manager, see <http://www.iodbc.org>.

To test your connection using the iODBC driver manager:

1. Run `iodbctest` or `iodbctestw`.
2. Optionally, if you do not remember the DSN, then type a question mark (?) to see a list of available DSNs.
3. Type the connection string for connecting to your data store, and then press ENTER. For more information, see [Using a Connection String](#) on page 57.

If the connection is successful, then the `SQL>` prompt appears.

Using the unixODBC Driver Manager

You can use the `isql` and `iusql` utilities to establish a test connection with your connector and your DSN. `isql` and `iusql` can only be used to test connections that use a DSN. Use `isql` to test how your connector works with an ANSI application, or use `iusql` to test how your connector works with a Unicode application.

Note:

There are 32-bit and 64-bit installations of the unixODBC driver manager available. If you have only one or the other installed, then the appropriate version of `isql` (or `iusql`) is available. However, if you have both 32- and 64-bit versions installed, then you need to make sure that you are running the version from the correct installation directory.

For more information about using the unixODBC driver manager, see <http://www.unixodbc.org>.

To test your connection using the unixODBC driver manager:

➤ Run `isql` or `iusql` by using the corresponding syntax:

- `isql [DataSourceName]`
- `iusql [DataSourceName]`

`[DataSourceName]` is the DSN that you are using for the connection.

If the connection is successful, then the `SQL>` prompt appears.

Note:

For information about the available options, run `isql` or `iusql` without providing a DSN.

Using a Connection String

For some applications, you might need to use a connection string to connect to your data source. For detailed information about how to use a connection string in an ODBC application, refer to the documentation for the application that you are using.

The connection strings in the following sections are examples showing the minimum set of connection attributes that you must specify to successfully connect to the data source. Depending on the configuration of the data source and the type of connection you are working with, you might need to specify additional connection attributes. For detailed information about all the attributes that you can use in the connection string, see [Connector Configuration Properties](#) on page 73.

DSN Connection String Example

The following is an example of a connection string for a connection that uses a DSN:

```
DSN=[DataSourceName]
```

[DataSourceName] is the DSN that you are using for the connection.

You can set additional configuration options by appending key-value pairs to the connection string. Configuration options that are passed in using a connection string take precedence over configuration options that are set in the DSN.

DSN-less Connection String Examples

Some applications provide support for connecting to a data source using a connector without a DSN. To connect to a data source without using a DSN, use a connection string instead.

The placeholders in the examples are defined as follows, in alphabetical order:

- *[ClientID]* is the Client ID to use when authenticating the connection to BigQuery.
- *[ClientSecret]* is the Client Secret to use when authenticating the connection to BigQuery.
- *[PortNumber]* is the number of the TCP port that the proxy server uses to listen for client connections.
- *[Project]* is the BigQuery project containing the data that you want to use.
- *[Server]* is the IP address or host name of the proxy server to which you are connecting.
- *[ServiceAccount]* is your service account email ID.

- *[ServiceKeyPath]* is the full path to a `.json` key file for service account authentication.
- *[Token]* is the refresh token that you obtain from Google for authorizing access to BigQuery.
- *[UserAccount]* is your user account email ID.
- *[UserKeyPath]* is the full path to a `.json` key file containing your refresh token, client ID, and client secret. For information about the required format of the `.json` file, see [Key File Path](#) on page 80.

Connecting to Google BigQuery using a User Account

The following is the format of a DSN-less connection string for a user account connection to Google BigQuery:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=1;RefreshToken=[Token];Catalog=  
[Project];ClientId=[ClientID];ClientSecret=[ClientSecret];
```

For example:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=1;RefreshToken=CH01pcNn/qFcYwU1JpkF_  
yyufYrqj4O4g7cdXvGgs-zT6;Catalog=testdata;ClientId=My_Client_  
Id;ClientSecret=My_Client_Secret;
```

As an alternative to providing your refresh token directly in the string, you can save your credentials in a `.json` key file and then provide the full path to that file in your string. In this case, the connection string must be written in the following format:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=0;Email=[UserAccount];KeyFilePath=  
[UserKeyPath];Catalog=[Project];
```

For example:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=0;Email=simba@gmail.com;  
KeyFilePath=C:\SecureFiles\UserKeyFile.json;Catalog=testdata;
```

Connecting to Google BigQuery using a Service Account

The following is the format of a DSN-less connection string for a service account connection to Google BigQuery:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=0;Email=[ServiceAccount];KeyFilePath=  
[ServiceKeyPath];Catalog=[Project];
```

For example:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=0;Email=application-service-  
account@iam.gserviceaccount.com;KeyFilePath=C:\SecureFiles\Se  
rviceKeyFile.json;Catalog=testdata;
```

Connecting to Google BigQuery through a Proxy Server

The following is the format of a DSN-less connection string for connecting to Google BigQuery with a user account through a proxy server:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=1;RefreshToken=[Token];Catalog=[Project];  
ProxyHost=[Server];ProxyPort=[PortNumber];
```

For example:

```
Driver=Simba Google BigQuery ODBC Connector;  
OAuthMechanism=1;RefreshToken=CH01pcNn/qFcYwUlJpkF_  
yyufYrqj404g7cdXvGgs-zT6;  
Catalog=testdata;ProxyHost=192.168.222.160;  
ProxyPort=8000;
```

Features

For more information on the features of the Simba Google BigQuery ODBC Connector, see the following:

- [Data Types](#) on page 60
- [Nested and Repeated Records](#) on page 64
- [Arrays](#) on page 65
- [Security and Authentication](#) on page 66
- [Catalog and Schema Support](#) on page 67
- [Large Result Set Support](#) on page 67
- [High-Throughput API](#) on page 69
- [Write-Back](#) on page 70
- [Positional Parameters](#) on page 70
- [ODBC Escapes](#) on page 70
- [Service Endpoints](#) on page 71

Data Types

The Simba Google BigQuery ODBC Connector supports many common data formats, converting between BigQuery data types and SQL data types.

- [Data type mappings: BigQuery to SQL](#)
- [Data type mappings: SQL to BigQuery](#)

The following table lists the supported data type mappings from BigQuery to SQL.

BigQuery Data Type	SQL Data Type
ARRAY	SQL_VARCHAR

BigQuery Data Type	SQL Data Type
	SQL_NUMERIC
	SQL_DECIMAL
BIGNUMERIC	<p>Note:</p> <p>The connector sends SQL_DECIMAL data to BigQuery as BIGNUMERIC data, because BigQuery does not support a DECIMAL data type.</p> <p>The connector always returns BIGNUMERIC data as SQL_NUMERIC data, and sends SQL_NUMERIC data to BigQuery as BIGNUMERIC data.</p>
BOOL	SQL_BIT
BOOLEAN	SQL_BIT
BYTES	SQL_VARBINARY
DATE	SQL_DATE
	SQL_TYPE_TIMESTAMP
DATETIME	<p>Note:</p> <p>For ODBC versions prior to ODBC 3, the connector uses SQL_TIMESTAMP.</p>
FLOAT64	SQL_DOUBLE

BigQuery Data Type	SQL Data Type
	SQL_VARCHAR or SQL_WVARCHAR.
GEOGRAPHY	<p>Note:</p> <ul style="list-style-type: none"> For information about whether GEOGRAPHY data is returned as SQL_VARCHAR or SQL_WVARCHAR, see Use SQL_WVARCHAR instead of SQL_VARCHAR on page 90. Geography data can only be inserted using specific functions. For more information, see: https://cloud.google.com/bigquery/docs/reference/standard-sql/geography_functions.
INTEGER	SQL_BIGINT
INTERVAL	SQL_VARCHAR
INT64	SQL_BIGINT
JSON	SQL_VARCHAR
	SQL_NUMERIC
	SQL_DECIMAL
NUMERIC	<p>Note:</p> <p>The connector sends SQL_DECIMAL data to BigQuery as NUMERIC data, because BigQuery does not support a DECIMAL data type.</p> <p>The connector always returns NUMERIC data as SQL_NUMERIC data, and sends SQL_NUMERIC data to BigQuery as NUMERIC data.</p>
RANGE	SQL_VARCHAR

BigQuery Data Type	SQL Data Type
	SQL_VARCHAR or SQL_WVARCHAR
STRING	<p>Note:</p> <p>For information about whether STRING data is returned as SQL_VARCHAR or SQL_WVARCHAR, see Use SQL_WVARCHAR instead of SQL_VARCHAR on page 90.</p>
STRUCT	SQL_VARCHAR
TIME	SQL_TIME
	SQL_TYPE_TIMESTAMP
TIMESTAMP	<p>Note:</p> <p>For ODBC versions prior to ODBC 3, the connector uses SQL_TIMESTAMP.</p>

The following table lists the supported data type mappings from SQL to BigQuery.

SQL Data Type	BigQuery Data Type
SQL_BIGINT	INT64
SQL_BIT	BOOL
SQL_CHAR	STRING
SQL_DATE	DATE
SQL_DECIMAL	NUMERIC
SQL_DOUBLE	FLOAT64
SQL_INTEGER	INT64

SQL Data Type	BigQuery Data Type
SQL_LONGVARBINARY	BYTES
SQL_LONGVARCHAR	STRING
SQL_NUMERIC	NUMERIC
SQL_SMALLINT	INT64
SQL_TIME	TIME
SQL_TIMESTAMP	TIMESTAMP
SQL_TINYINT	INT64
SQL_TYPE_DATE	DATE
SQL_TYPE_TIME	TIME
SQL_TYPE_TIMESTAMP	TIMESTAMP
SQL_VARBINARY	BYTES
SQL_VARCHAR	STRING
SQL_WLONGVARCHAR	STRING
SQL_WVARCHAR	STRING

Nested and Repeated Records

The Simba Google BigQuery ODBC Connector partially supports nested and repeated records.

In Standard SQL, the record is returned as a BigQuery string, and converted to SQL_VARCHAR. The Standard SQL syntax represents the sub-components of record data as nested sub-types. In the example below, `city` and `years` belong to the base record type of `address`, and `name` does not.

```
{  
  "v": { // "column" object
```

```
    "f": [
      { // "address" value
        "v": [ // "address" array
          { // "city" value
            "v":
              "Vancouver"
          },
          { // "years" value
            "v": "5"
          }
        ]
      },
      { // "name" value
        "v": "Google"
      }
    ]
  }
}
```

In Legacy SQL, the record is flattened by BigQuery before it is returned by the connector. The query returns the data as the schema of a flat table. All STRUCT members are their own columns, and all ARRAY members are expanded into as many rows as there are array elements.

Arrays

The Simba Google BigQuery ODBC Connector fully supports ARRAY data types. The connector returns the base ARRAY type as a text representation of the JSON array object.

For example, the SQL statement `SELECT [1,2,3]` returns the following JSON:

```
{
```

```
"v": [
  {
    "v": "1",
  },
  {
    "v": "2",
  },
  {
    "v": "3"
  }
]
```

Security and Authentication

To protect data from unauthorized access, BigQuery data stores require all connections to be authenticated using the OAuth 2.0 protocol and encrypted using TLS 1.2 with one-way authentication. The Simba Google BigQuery ODBC Connector protects your data by providing support for these authentication protocols and further obscuring data from unwanted access by fetching it in a non-text format. The data is compressed using zlib and encrypted using TLS.

The connector provides mechanisms that allow you to complete an OAuth 2.0 authentication flow using a Google user account or a Google service account. The connector retrieves a token based on the account credentials specified in your DSN or connection string, and then uses the token to authenticate the connection to BigQuery. For detailed configuration instructions, see [Configuring Authentication on Windows](#) on page 12 or [Configuring Authentication on a Non-Windows Machine](#) on page 43.

Additionally, the connector automatically encrypts all connections with TLS. TLS encryption protects data and credentials when they are transferred over the network, and provides stronger security than authentication alone. By default, the connector uses the trusted CA certificates file that is included during installation, but you can configure the connector to use a different file by setting the `TrustedCertificates` option (the `TrustedCerts` property). On Windows machines, you can configure the connector to use the system trust store by setting the `Use System Trust Store` option (the `UseSystemTrustStore` property). For detailed configuration

instructions, see [Creating a Data Source Name on Windows](#) on page 9 or [Creating a Data Source Name on a Non-Windows Machine](#) on page 37.

Catalog and Schema Support

The Simba Google BigQuery ODBC Connector supports both catalogs and schemas to make it easy for the connector to work with various ODBC applications. Projects are mapped to catalogs, and table datasets are mapped to schemas. For more information, see [Catalog \(Project\)](#) on page 76.

Large Result Set Support

The Simba Google BigQuery ODBC Connector supports the `AllowLargeResults` option in BigQuery job configurations, enabling the connector to execute queries with result sizes that would exceed the BigQuery standard size limits.

Note:

For more information about BigQuery maximum result sizes, see "Quotas and Limits" in the Google BigQuery documentation:
https://cloud.google.com/bigquery/quotas#query_jobs.

The `AllowLargeResults` option is always enabled when executing with the Standard SQL language dialect. For more information, see the following sections in this documentation:

- [Allow Large Result Sets](#) on page 75
- [Language Dialect](#) on page 80

Note:

When the connector connection is configured to use large results, all queries on that connection are executed indiscriminately as large results queries, and their results are stored in a table in the large results dataset.

When the connector is configured to allow large results and a query is executed, the connector configures a job to create a temporary table when the query is executed. This temporary table exists under the dataset ID specified in the Dataset Name for Large Results Sets field (or the `LargeResultsDataSetId` property). These tables are temporary and exist for a limited time. The time for which a temporary table exists is dependent on the table expiration default time in its parent dataset.

Note:

For more information about BigQuery datasets, see "Resource: Dataset" in the Google BigQuery documentation:

<https://cloud.google.com/bigquery/docs/reference/rest/v2/datasets#Dataset>.

It is recommended that the dataset you want to use for storing temporary tables is already present in the region and project in which you are executing your query.

If it is not, the connector can create these datasets before executing the query. If there is a value in the `LargeResultsDataSetId` property, and that dataset is not present in the project and region in which the query is being executed, then the connector attempts to create a dataset with that name in the project the connector is currently configured with, for more information, see [Catalog \(Project\)](#) on page 76. The default table expiration time, in milliseconds, for that dataset is taken from the value in the `Default temp table expiration time (ms)` field (or the `LargeResultsTempTableExpirationTime` property).

Note:

There is a limitation of the BigQuery API when creating datasets, where the dataset created by the connector is always created in the US region. As a workaround, use the BigQuery Cloud Console or the `datasets.insert` BigQuery API to create the dataset in the region of your choosing. For more information, see the Google BigQuery documentation:

- <https://cloud.google.com/bigquery/docs/datasets-intro>
- <https://cloud.google.com/bigquery/docs/datasets>
- <https://cloud.google.com/bigquery/docs/updating-datasets>

Note:

As an alternative to specifying a `LargeResultsDataSetId` value, you can toggle the `UseDefaultLargeResultsDataset` property to on (set to 1). In this case, the connector uses a default dataset value of `_bqodbc_temp_tables`. This is a hidden dataset and is not displayed in the BigQuery Cloud Console view. For more information, see [Use Default `_bqodbc_temp_tables` Large Results Dataset](#) on page 90.

For more information about large result sets and the limitations of this feature, see the following sections in the BigQuery documentation:

- "Queries" in *Quota Policy*: <https://developers.google.com/bigquery/quota-policy>.
- "Returning large query results" in *Query Data*:
<https://developers.google.com/bigquery/querying-data>.

High-Throughput API

The High-Throughput API enables the connector to leverage the BigQuery Storage API, allowing higher data throughput than the standard REST API. With this API, the connector can handle large result sets more efficiently. For more information about the Storage API, see "BigQuery Storage API Overview" in the Google BigQuery documentation: <https://cloud.google.com/bigquery/docs/reference/storage/>.

The connector extrapolates the number of pages needed to retrieve all the results. If the number of pages exceed the defined thresholds, the connector uses the BigQuery Storage API.

You can customize the thresholds for using the BigQuery Storage API. For information about the configuration options used to determine when the API is used, see the following:

- [Allow High-Throughput API for Large Results queries](#) on page 75
- [Activation Threshold for High-Throughput API](#) on page 74

Requirements

Before you can use the High-Throughput API, you must make certain that your system meets the following requirements:

- Your authentication requires the `devstorage.read_only` scope at minimum to use the High-Throughput API. For more information, see <https://developers.google.com/identity/protocols/oauth2/scopes>.
- The BigQuery project that you are querying must have the BigQuery Storage API enabled. For more information, see "Enabling the API" in the Google BigQuery documentation: https://cloud.google.com/bigquery/docs/reference/storage/#enabling_the_api.

Important:

Pricing for the BigQuery Storage API is different than pricing for the standard API. For more information, see "BigQuery Storage API Pricing" in the Google BigQuery documentation: <https://cloud.google.com/bigquery/pricing#storage-api>.

- On Windows, the connector must not be configured to use the trust store, that is, the Use System Trust Store check box must not be selected or the `UseSystemTrustStore` property must not be set to 1.
- To enable the High-Throughput API for use with large result sets, the Allow High-Throughput API for Large Results queries check box must be selected or the `AllowHtapiForLargeResults` property must be set to 1.

The INTERVAL data type is not supported on the Read API. When retrieving data from a column of the INTERVAL type, the connector returns an error. To enable the connector to fallback to the REST API, set `UnsupportedHTAPIFallback` to 1.

Write-Back

The Simba Google BigQuery ODBC Connector supports Data Manipulation Language (DML) statements such as INSERT, MERGE, and DELETE.

For example, the following INSERT statement is supported:

```
INSERT INTO MyTable (Col1, Col2) VALUES ("Key", "Value");
```

The connector also supports Data Definition Language (DDL) statements. Be aware that BigQuery supports specific syntax for DDL statements, and your statements must be written in that syntax. For more information, see "Using Data Definition Language Statements" in Google BigQuery's *Standard SQL Query Reference*: <https://cloud.google.com/bigquery/docs/data-definition-language>.

Positional Parameters

A parameterized query contains placeholders that are used for parameters. The values of those parameters are supplied at execution time.

The Simba Google BigQuery ODBC Connector supports SQL positional parameters. Parameters are specified in queries with a question mark (?).

For example, the following parameterized query is supported:

```
SELECT * FROM MyTable WHERE Col1=?
```

ODBC Escapes

The Simba Google BigQuery ODBC Connector supports a subset of the ODBC escape syntaxes. For a complete list of the escapes that the connector supports, call `SQLGetInfo` from the connector.

For more information about ODBC escapes, see "ODBC Escape Sequences" in the Programmer's Reference: [https://msdn.microsoft.com/en-us/library/ms711838\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/ms711838(v=vs.85).aspx).

For information about known issues that occur for specific ODBC escape use cases, see the "Known Issues" section in the *Magnitude Simba Google BigQuery ODBC Data Connector Release Notes*.

Service Endpoints

The Simba Google BigQuery ODBC Connector uses the following API service endpoints:

API Service	Service Endpoint
Default server name	<code>www.googleapis.com</code>
Default API URL	<code>https://bigquery.googleapis.com/bigquery/v2</code>
Default access token request URL (User authentication)	<code>https://oauth2.googleapis.com/token</code>
Default access token request URL (Service authentication)	<code>https://accounts.google.com/o/oauth2/auth?</code>
Default OAuth scope	<code>https://www.googleapis.com/auth/cloud-platform</code>
Google Drive scope	<code>https://www.googleapis.com/auth/drive</code>
Google Client X509 certification URL	<code>https://www.googleapis.com/robot/v1/metadata/x509/</code>

API Service	Service Endpoint
Storage API URL	<code>https://bigquerystorage.googleapis.com/</code>

In addition, if you are behind a proxy, you must make sure that the proxy allows communication to `crl.pki.goog`, `crls.pki.goog`, and `ocsp.pki.goog`.

Connector Configuration Properties

Connector Configuration Options lists the configuration options available in the Simba Google BigQuery ODBC Connector alphabetically by field or button label. Options having only key names, that is, not appearing in the user interface of the connector, are listed alphabetically by key name.

When creating or configuring a connection from a Windows machine, the fields and buttons described below are available in the following dialog boxes:

- Simba Google BigQuery ODBC Connector DSN Setup
- Advanced Options
- Logging Options

When using a connection string or configuring a connection from a non-Windows machine, use the key names provided below.

Configuration Options Appearing in the User Interface

The following configuration options are accessible via the Windows user interface for the Simba Google BigQuery ODBC Connector, or via the key name when using a connection string or configuring a connection from a Linux or macOS computer:

- [Activation Threshold for High-Throughput API on page 74](#)
- [Additional Projects on page 74](#)
- [Allow High-Throughput API for Large Results queries on page 75](#)
- [Allow Large Result Sets on page 75](#)
- [Catalog \(Project\) on page 76](#)
- [Dataset Name For Large Result Sets on page 77](#)
- [Dataset on page 77](#)
- [Default String Column Length on page 78](#)
- [Email on page 78](#)
- [Enable High-Throughput API on page 78](#)
- [Enable Session on page 79](#)
- [OAuth Mechanism on page 83](#)
- [Path to CMEK on page 84](#)
- [Proxy Host on page 85](#)
- [Proxy Password on page 85](#)
- [Proxy Port on page 85](#)
- [Proxy Username on page 86](#)
- [Query Properties on page 86](#)
- [Ratio of Results to Rows Per Block on page 87](#)
- [Refresh Token on page 88](#)
- [Request Google Drive Scope Access on page 88](#)
- [Rows Fetched Per Block on page 88](#)
- [SessionLocation on page 89](#)
- [Default temp table expiration time](#)

- [Key File Path](#) on page 80
- [Language Dialect](#) on page 80
- [Log Level](#) on page 81
- [Log Path](#) on page 82
- [Max File Size](#) on page 82
- [Max Number Files](#) on page 82
- [Minimum TLS](#) on page 83
- [\(ms\)](#) on page 89
- [Trusted Certificates](#) on page 89
- [Use Default _bqodbc_temp_tables Large Results Dataset](#) on page 90
- [Use SQL_WVARCHAR instead of SQL_VARCHAR](#) on page 90
- [Use System Trust Store](#) on page 91

Activation Threshold for High-Throughput API

Key Name	Default Value	Required
HTAPI_ActivationThreshold	3	No

Description

The minimum total pages (ratio of total rows to rows in the first page) required to activate reading through the High-Throughput API.

Important:

The `HTAPI_MinActivationRatio` property has been deprecated and the `HTAPI_ActivationThreshold` property is now the primary alias. The primary alias has precedence and is used when both are present.

Additional Projects

Key Name	Default Value	Required
AdditionalProjects	None	No

Description

A comma-separated list of public BigQuery projects that the connector can access and use as catalogs. These projects are available as catalogs in metadata functions.

Allow Large Result Sets

Key Name	Default Value	Required
<code>AllowLargeResults</code>	Clear (0)	No

Description

This option specifies the connector's response to query results larger than the BigQuery maximum result sizes when using Legacy SQL.

- Enabled (1): The connector allows query results that are larger than the BigQuery maximum result sizes.
- Disabled (0): The connector returns an error when query results are larger than the BigQuery maximum result sizes.

Note:

- If this option is enabled, you must also specify a dataset for storing the temporary tables. For more information see [Dataset Name For Large Result Sets](#) on page 77.
- For more information about BigQuery maximum result sizes, see "Quotas and Limits" in the Google BigQuery documentation: https://cloud.google.com/bigquery/quotas#query_jobs.

For additional information on SQL see [Language Dialect](#) on page 80.

Allow High-Throughput API for Large Results queries

Key Name	Default Value	Required
<code>AllowHtapiForLargeResults</code>	Clear (0)	No

Description

This option specifies whether the connector uses the BigQuery High-Throughput API for large result sets. For detailed information about the High-Throughput API, see [High-Throughput API](#) on page 69.

- Enabled (1): The connector uses the High-Throughput API for large result sets that exceed the activation threshold for High-Throughput API.

- Disabled (0): The connector does not use the High-Throughput API for large result sets.

Important:

Pricing for the High-Throughput API is different than pricing for the standard REST API. For more information, see "BigQuery Storage API Pricing" in the Google BigQuery documentation:

<https://cloud.google.com/bigquery/pricing#storage-api>.

Important:

The `EnableHTAPI` property has been deprecated and the `AllowHtapiForLargeResults` property is now the primary alias. The primary alias has precedence and is used when both are present.

Catalog (Project)

Key Name	Default Value	Required
Catalog	None	Yes

Description

The name of your BigQuery project. This project is the default project that the Simba Google BigQuery ODBC Connector queries against, and is also the project that is billed for queries that are run using the DSN.

Simba ODBC Connector for Google BigQuery supports multiple catalogs, the equivalent of Google BigQuery projects.

For queries, tables in the projection list must be fully qualified, in the format of `catalog.schema.table`. If the catalog is not specified, the connector will assume the project specified by the **Catalog** connection option.

For catalog functions, to retrieve information from the desired catalog, the ODBC `SQLSetConnectAttr` method must be called with `SQL_ATTR_CURRENT_CATALOG` set to the desired catalog.

Note:

To use the High-Throughput API, the specified project must have the BigQuery Storage API enabled. For more information, see "Enabling the API" in the Google BigQuery documentation:

https://cloud.google.com/bigquery/docs/reference/storage/#enabling_the_api.

Dataset Name For Large Result Sets

Key Name	Default Value	Required
LargeResultsDataSetId	None (but see Use Default_bqodbc_temp_tables Large Results Dataset on page 90)	No

Description

The ID of the BigQuery dataset that you want to use to store temporary tables for large result sets. Only specify a value for this option if you want to enable support for large result sets.

Note:

- If the `UseDefaultLargeResultsDataset` property is enabled, it overrides this value.
- If this dataset does not exist and the data store specifies the US region, the connector creates the dataset.
- If you want to use large result sets with Legacy SQL, you must also enable the **Allow Large Result Sets** option. See [Allow Large Result Sets on page 75](#).

Dataset

Key Name	Default Value	Required
DefaultDataset	None	No

Description

The name of a dataset that the connector queries by default.

Specifying a default dataset enables you to use unqualified table names in SQL statements. The connector treats unqualified tables as part of the default dataset. Additionally, it treats the default dataset as part of the project that is being billed. For information about specifying the project to bill, see [Catalog \(Project\)](#) on page 76.

Default String Column Length

Key Name	Default Value	Required
DefaultStringColumnLength	16384	No

Description

The maximum number of characters that can be contained in STRING columns.

Email

Key Name	Default Value	Required
Email	None	No

Description

When configuring Service Authentication, set this option to the service account email ID.

Enable High-Throughput API

Key Name	Default Value	Required
EnableHTAPI	Clear (0)	No

Description

This option specifies whether the connector uses the BigQuery High-Throughput API for large result sets. For detailed information about the High-Throughput API, see [High-Throughput API](#) on page 69.

- Enabled (1): The connector uses the High-Throughput API for large result sets that exceed Activation Threshold for High-Throughput API.
- Disabled (0): The connector does not use the High-Throughput API for large result sets.

Important:

Pricing for the BigQuery Storage API is different than pricing for the standard API. For more information, see "BigQuery Storage API Pricing" in the Google BigQuery documentation: <https://cloud.google.com/bigquery/pricing#storage-api>.

Important:

This property has been deprecated and will be removed at a future release. The `AllowHtapiForLargeResults` property is now the primary alias. The primary alias has precedence and is used when both are present.

Enable Session

Key Name	Default Value	Required
<code>EnableSession</code>	Disabled (0)	No

Description

This property specifies whether the connector creates a session ID from the first executed query on that connection. The session ID is passed to all subsequent executed queries as a BigQuery connection property.

- Enabled (1): The connector creates a session ID from the first executed query on that connection.
- Disabled (0): The connector does not create a session ID.

Note:

- A session ID passed through the `QueryProperties` list is treated as a direct pass-through and is not specially handled by the connector.
- The `EnableSession` property is required when using transactions.

For information on BigQuery connection properties, see the Google BigQuery documentation:

<https://cloud.google.com/bigquery/docs/reference/rest/v2/ConnectionProperty>.

Key File Path

Key Name	Default Value	Required
KeyFilePath	None	Yes, if OAuth Mechanism is set to Service Authentication (OAuthMechanism=0) and KeyFile is not set.

Description

When configuring Service Authentication, set this option to the full path to the `.json` key file that is used to authenticate the service account email address.

When configuring User Authentication with a `.json` key file, set this option to the full path to the `.json` key file containing your OAuth 2.0 credentials. The file must define a JSON object of type `authorized_user` containing the refresh token, client ID, and client secret associated with your user account. For example, the `.json` key file must be written in the following format:

```
{
  "type": "authorized_user",
  "client_id": "[YourClientID]",
  "client_secret": "[YourClientSecret]",
  "refresh_token": "[YourRefreshToken]"
}
```

Language Dialect

Key Name	Default Value	Required
SQLDialect	Standard SQL (1)	No

Description

This option specifies whether the connector executes queries using standard SQL syntax or the legacy BigQuery SQL syntax.

- Standard SQL (1): The connector uses standard SQL.
- Legacy SQL (0): The connector uses legacy SQL.

Log Level

Key Name	Default Value	Required
LogLevel	OFF (0)	No

Description

Use this property to enable or disable logging in the connector and to specify the amount of detail included in log files.

Important:

- Only enable logging long enough to capture an issue. Logging decreases performance and can consume a large quantity of disk space.
- When logging with connection strings and DSNs, this option only applies to per-connection logs.

Set the property to one of the following values:

- OFF (0): Disable all logging.
- FATAL (1): Logs severe error events that lead the connector to abort.
- ERROR (2): Logs error events that might allow the connector to continue running.
- WARNING (3): Logs events that might result in an error if action is not taken.
- INFO (4): Logs general information that describes the progress of the connector.
- DEBUG (5): Logs detailed information that is useful for debugging the connector.
- TRACE (6): Logs all connector activity.

When logging is enabled, the connector produces the following log files at the location you specify in the Log Path (`LogPath`) property:

- A `simbabigqueryodbcdriver.log` file that logs connector activity that is not specific to a connection.
- A `simbabigqueryodbcdriver_connection_[Number].log` file for each connection made to the database, where `[Number]` is a number that identifies each log file. This file logs connector activity that is specific to the connection.

Log Path

Key Name	Default Value	Required
LogPath	None	Yes, if logging is enabled.

Description

The full path to the folder where the connector saves log files when logging is enabled.

Important:

When logging with connection strings and DSNs, this option only applies to per-connection logs.

Max File Size

Key Name	Default Value	Required
LogFileSize	20971520	No

Description

The maximum size of each log file in bytes. After the maximum file size is reached, the connector creates a new file and continues logging.

If this property is set using the Windows UI, the entered value is converted from megabytes (MB) to bytes before being set.

Important:

When logging with connection strings and DSNs, this option only applies to per-connection logs.

Max Number Files

Key Name	Default Value	Required
LogFileCount	50	No

Description

The maximum number of log files to keep. After the maximum number of log files is reached, each time an additional file is created, the connector deletes the oldest log file.

Important:

When logging with connection strings and DSNs, this option only applies to per-connection logs.

Minimum TLS

Key Name	Default Value	Required
Min_TLS	TLS 1.2 (1.2)	No

Description

The minimum version of TLS/SSL that the connector allows the data store to use for encrypting connections. For example, if TLS 1.1 is specified, TLS 1.0 cannot be used to encrypt connections.

- TLS 1.0 (1.0): The connection must use at least TLS 1.0.
- TLS 1.1 (1.1): The connection must use at least TLS 1.1.
- TLS 1.2 (1.2): The connection must use at least TLS 1.2.

OAuth Mechanism

Key Name	Default Value	Required
OAuthMechanism	User Authentication (1)	No

Description

The OAuth 2.0 authentication mechanism used to authenticate the connector.

- Service Authentication (0): The connector authenticates as a service, through a Google service account.
- User Authentication (1): The connector authenticates as a user, through a Google user account.

- Application Default Credentials Authentication (3): The connector authenticates as a user, through a `GOOGLE_APPLICATION_CREDENTIALS` environment variable.
- External Account Authentication (4): The connector authenticates using workforce identity federation.

Note:

- When the connector is configured to use External Account Authentication (`OAuthMechanism=4`), connection properties are considered in the following precedence:
 1. `KeyFile`
 2. `KeyFilePath` (or `KeyFilePath_Enc` if the key file is not set)
 3. `BYOID_` properties

Path to CMEK

Key Name	Default Value	Required
	None.	
<code>KMSKeyName</code>	The connector uses the default encryption key from Google.	No

Description

The resource ID of the customer-managed encryption key (CMEK) that you want the connector to use when executing queries. When this property is not set, the connector uses the default encryption key from Google.

For information about CMEKs and Cloud KMS encryption, see "Protecting Data with Cloud KMS Keys" in the Google BigQuery documentation:

<https://cloud.google.com/bigquery/docs/customer-managed-encryption>.

⚠ Important:

- The `KMSKeyName` property is used only when the connector is configured to use the destination tables.
- Do not set this property unless you are certain that you are specifying the correct CMEK. If you execute an INSERT statement with an incorrect CMEK, the connector returns an error or corrupts the table.
- When this property is set, the connector uses the specified CMEK for all queries.

Proxy Host

Key Name	Default Value	Required
<code>ProxyHost</code>	None	Yes, if connecting through a proxy server.

Description

The host name or IP address of a proxy server that you want to connect through.

Proxy Password

Key Name	Default Value	Required
<code>ProxyPwd</code>	None	Yes, if connecting to a proxy server that requires authentication.

Description

The password that you use to access the proxy server.

Proxy Port

Key Name	Default Value	Required
<code>ProxyPort</code>	None	Yes, if connecting through a proxy server.

Description

The number of the port that the proxy server uses to listen for client connections.

Proxy Username

Key Name	Default Value	Required
ProxyUid	None	Yes, if connecting to a proxy server that requires authentication.

Description

The user name that you use to access the proxy server.

Query Properties

Key Name	Default Value	Required
QueryProperties	None	Yes, if using a default project.

Description

This option enables you to pass properties through to the server when inserting a job. Properties set in this manner are used for all queries in a connection. The `QueryProperties` list must be in the following form:

```
key1=value1, key2=value2, ..., keyN=valueN
```

Note:

To configure the connector to use a default project for datasets, set the `dataset_project_id` property in `QueryProperties` of the connection string to the desired project.

This option also supports the `time_zone` connection property in the following form:

```
time_zone=America/Los_Angeles
```

For detailed information, see "Supported Time Zone Values" in the Google BigQuery documentation: https://cloud.google.com/dataprep/docs/html/Supported-Time-Zone-Values_66194188.

Important:

The `QueryProperties` property corresponds to the BigQuery "connectionProperties" field present in both the `QueryRequest` and `JobConfigurationQuery` objects. Each item in the comma-separated list is translated to a `ConnectionProperty` object. For detailed information, see the Google BigQuery documentation for these objects:

- `ConnectionProperty`:
<https://cloud.google.com/bigquery/docs/reference/rest/v2/ConnectionProperty>
- `QueryRequest`:
<https://cloud.google.com/bigquery/docs/reference/rest/v2/jobs/query#QueryRequest>
- `JobConfigurationQuery`:
<https://cloud.google.com/bigquery/docs/reference/rest/v2/Job#JobConfigurationQuery>

Ratio of Results to Rows Per Block

Key Name	Default Value	Required
HTAPI_MinActivationRatio	3	No

Description

The minimum total pages required to activate reading through the High-Throughput API.

Important:

This property has been deprecated and the `HTAPI_ActivationThreshold` property is now the primary alias. The primary alias has precedence and is used when both are present.

Refresh Token

Key Name	Default Value	Required
<code>RefreshToken</code>	None	Yes, if authenticating through a user account.

Description

The refresh token that you obtain from Google for authorizing access to BigQuery.

When you configure a DSN with the Windows connector, the refresh token is generated automatically after you provide the confirmation code.

When you configure a DSN with the Linux or macOS versions of the connector, you can use the Google OAuth 2.0 Playground to generate the token. For more information, see [Using a Google User Account](#) on page 43.

Request Google Drive Scope Access

Key Name	Default Value	Required
<code>RequestGoogleDriveScope</code>	Clear (0)	No

Description

This option specifies whether the connector requests access to Google Drive. Allowing the connector to access Google Drive enables support for federated tables that combine BigQuery data with data from Google Drive.

- Enabled (1): The connector requests access to Google Drive.
- Disabled (0): The connector does not request access to Google Drive.

Rows Fetched Per Block

Key Name	Default Value	Required
<code>RowsFetchedPerBlock</code>	100000	No

Description

The maximum number of rows that the connector can fetch for each data request.

SessionLocation

Key Name	Default Value	Required
SessionLocation	None	No

Description

This option specifies the region or location in which the queries executed by the connection will be executed. For more information on locations in BigQuery, consult the Google BigQuery documentation: [BigQuery locations](#).

Default temp table expiration time (ms)

Key Name	Default Value	Required
LargeResultsTempTableExpirationTime	3600000	No

Description

The default table expiration time, in milliseconds, for large results data sets created by the connector.

Trusted Certificates

Key Name	Default Value	Required
TrustedCerts	The <code>cacerts.pem</code> file in the <code>\lib</code> subfolder within the connector's installation directory. The exact file path varies depending on the version of the connector that is installed. For example, the path for the Windows connector is different from the path for the macOS connector.	No

Description

The full path of the `.pem` file containing trusted CA certificates, for verifying the server.

If this option is not set, then the connector defaults to using the trusted CA certificates `.pem` file installed by the connector. To use the trusted CA certificates in the `.pem` file, set the `UseSystemTrustStore` property to 0 or clear the Use System Trust Store check box in the SSL Options dialog.

Use Default `_bqodbc_temp_tables` Large Results Dataset

Key Name	Default Value	Required
<code>UseDefaultLargeResultsDataset</code>	Clear (0)	No

Description

This option specifies whether the connector uses a default dataset to store temporary tables for large result sets if no dataset is specified and the data store specifies the US region.

- Enabled (1): The connector uses a default large result dataset of `_bqodbc_temp_tables`.
- Disabled (0): The connector does not use a default large result dataset. If no dataset is specified, large result support is not enabled.

Note:

- If this value is specified, it overrides the `LargeResultsDatasetId` property.
- If this option is selected, the data store specifies the US region, and the `_bqodbc_temp_tables` dataset does not exist, the connector creates this dataset.
- If you want to use large result sets with Legacy SQL, you must also enable the **Allow Large Result Sets** option. See [Allow Large Result Sets](#) on page 75.

Use SQL_WVARCHAR instead of SQL_VARCHAR

Key Name	Default Value	Required
<code>UseWVarChar</code>	Clear (0)	No

Description

This option specifies how data types are mapped to SQL.

- Enabled (1): The connector returns data as SQL_WVARCHAR data instead of SQL_VARCHAR data.
- Disabled (0): The connector returns data as SQL_VARCHAR data.

Note:

This option applies only to result set columns that the connector would normally return as SQL_VARCHAR columns. It does not convert all columns into SQL_WVARCHAR.

Use System Trust Store

Key Name	Default Value	Required
UseSystemTrustStore	Clear (0)	No

Description

This option specifies whether to use a CA certificate from the system trust store, or from a specified .pem file.

- Enabled (1): The connector verifies the connection using a certificate in the system trust store.
- Disabled (0): The connector verifies the connection using a specified .pem file. For information about specifying a .pem file, see [Trusted Certificates](#) on page 89.

Note:

This option is only available on Windows.

Configuration Options Having Only Key Names

The following configuration options do not appear in the Windows user interface for the Simba Google BigQuery ODBC Connector. They are accessible only when you use a connection string or configure a connection on macOS or Linux.

The following configuration options do not appear in the Windows user interface for the Simba Google BigQuery ODBC Connector. They are accessible only when you use a connection string.

- [BYOID_AudienceUri](#) on page 92
- [BYOID_CredentialSource](#) on page 93
- [BYOID_PoolUserProject](#) on page 94
- [BYOID_SubjectTokenType](#) on page 94
- [BYOID_TokenUri](#) on page 95
- [ClientId](#) on page 95
- [ClientSecret](#) on page 95
- [Driver](#) on page 96
- [FilterTablesOnDefaultDataset](#) on page 96
- [IgnoreTransactions](#) on page 98
- [KeyFile](#) on page 99
- [MaxThreads](#) on page 99
- [PrivateServiceConnectUris](#) on page 99
- [SessionLocation](#) on page 89
- [Timeout](#) on page 102
- [UnsupportedHTAPIFallback](#) on page 102
- [UseQueryCache](#) on page 102

The following connector-wide property must be configured as a Windows Registry key value, or in the `simba.googlebigqueryodbc.ini` file for macOS or Linux.

- [MaxThreads](#) on page 99

BYOID_AudienceUri

Key Name	Default Value	Required
BYOID_AudienceUri	None	Yes, if OAuth Mechanism is set to External Account Authentication (OAuthMechanism=4) and other BYOID_ properties, or KeyFile or KeyFilePath are not set.

Description

When configuring External Account Authentication, set this option to the full path of the full audience URI. This option corresponds to the `audience` property in the configuration file. For example, the URI must be written in the following format:

```
//iam.googleapis.com/locations/${LOCATION}/workforcePools/${PROVIDER_POOL_ID}/providers/${PROVIDER_ID}
```

BYOID_CredentialSource

Key Name	Default Value	Required
BYOID_CredentialSource	None	Yes, if OAuth Mechanism is set to External Account Authentication (OAuthMechanism=4) and other BYOID_ properties, or KeyFile or KeyFilePath are not set.

Description

When configuring External Account Authentication, set this option to the full path of the `.json` configuration file that is used to specify the source from which to retrieve a subject token to exchange for an access token. This option corresponds to the `credential_source` property in the configuration file.

Note:

- The key file must be in raw `.json` format.
- Only "file" ODBC credential sources are supported (files from which the subject token can be read).
- For more information about generating configuration files, see "Generate a Configuration File" in the Google Cloud documentation: https://cloud.google.com/iam/docs/workforce-obtaining-short-lived-credentials#generate_a_configuration_file.

BYOID_PoolUserProject

Key Name	Default Value	Required
BYOID_PoolUserProject	None	Yes, if OAuth Mechanism is set to External Account Authentication (OAuthMechanism=4) and other BYOID_ properties, or KeyFile or KeyFilePath are not set.

Description

When configuring External Account Authentication, set this option to the full path of the project ID or name to use for external account authentication. This option corresponds to the `workforce_pool_user_project` key in the configuration file.

BYOID_SubjectTokenType

Key Name	Default Value	Required
BYOID_SubjectTokenType	<code>urn:ietf:params:oauth:token-type:id_token</code>	Yes, if OAuth Mechanism is set to External Account Authentication (OAuthMechanism=4) and other BYOID_ properties, or KeyFile or KeyFilePath are not set.

Description

When configuring External Account Authentication, set this option to the full path of the subject token type. This option corresponds to the `subject_token_type` key in the configuration file.

BYOID_TokenUri

Key Name	Default Value	Required
BYOID_TokenUri	https://sts.googleapis.com/v1/to ken	Yes, if OAuth Mechanism is set to External Account Authentication (OAuthMechanism=4) and other BYOID_ properties, or KeyFile or KeyFilePath are not set.

Description

When configuring External Account Authentication, set this option to the full path of the STS token URL to query when retrieving a short-lived access token. This option corresponds to the `token_url` key in the configuration file.

ClientId

Key Name	Default Value	Required
ClientId	Branded default Client ID	No

Description

The default value depends on the package that you received. It is recommended to use your own Client ID and Client Secret values. When using User Account, the value of Client ID should be the value that refresh token was created with.

ClientSecret

Key Name	Default Value	Required
ClientSecret	***	No

Description

The default value depends on the package that you received. It is recommended to use your own Client ID and Client Secret values. When using User Account, the value of Client Secret should be the value that refresh token was created with.

Driver

Key Name	Default Value	Required
Driver	Simba BigQuery ODBC Driver when installed on Windows, or the absolute path of the connector shared object file when installed on a non-Windows machine.	Yes

Description

On Windows, the name of the installed connector (Simba BigQuery ODBC Driver).

On other platforms, the name of the installed connector as specified in `odbcinst.ini`, or the absolute path of the connector shared object file.

FilterTablesOnDefaultDataset

Key Name	Default Value	Required
FilterTablesOnDefaultDataset	FALSE	No

Description

This option determines whether the connector filters tables in the `SQLTables` call and columns in the `SQLColumns` call to return only tables and columns that belong to the default dataset.

- **FALSE:** The connector returns all tables in the `SQLTables` call and all columns in the `SQLColumns` call.
- **TRUE:** The connector only returns tables and columns that belong to the default dataset.

Note:

To filter tables and columns, you must define a default dataset. For details, see [Dataset](#) on page 77.

When this option is set to `TRUE`, the connector behaves as described below for the functions `SQLTables` and `SQLColumns`.

For the function `SQLTables`:

Catalog	Schema	Table	Table Type	Returned List
NULL	NULL	NULL or %	NULL or %	All tables that belong to the default dataset under the default catalog
%	NULL	NULL or %	NULL or %	All tables that belong to the default dataset under all catalogs
NULL	%	NULL or %	NULL or %	All tables that belong to all schemas under the default catalog
%	%	NULL or %	NULL or %	All tables that belong to all schemas under all catalogs
NULL	<schema>	NULL or %	NULL or %	All tables that belong to the specified schema under the default catalog
<catalog>	<schema>	NULL or %	NULL or %	All tables that belong to the specified schema under the specified catalog

For the function `SQLColumns`:

Catalog	Schema	Table	Column	Returned List
NULL	NULL	NULL	NULL	All columns of all tables that belong to the default dataset under the default catalog
<catalog>	NULL	NULL	NULL	All columns of all tables that belong to the default dataset under the specified catalog
NULL	%	NULL	NULL	All columns of all tables that belong to all datasets under the default catalog
<catalog>	%	NULL	NULL	All columns of all tables that belong to all datasets under the specified catalog
NULL	<schema>	NULL	NULL	All columns of all tables that belong to the specified dataset under the default catalog
<catalog>	<schema>	NULL	NULL	All columns of all tables that belong to the specified dataset under the specified catalog

IgnoreTransactions

Key Name	Default Value	Required
IgnoreTransactions	0	No

Description

This option determines whether the connector ignores attempts to perform transactions.

- 0: Attempts to perform transactions produce a user alert.
- 1: The connector ignores attempts to perform transactions. No alerts are generated for these calls.

KeyFile

Key Name	Default Value	Required
KeyFile	None	Yes, if OAuth Mechanism is set to Service Authentication (OAuthMechanism=0) and KeyFilePath is not set.

Description

When configuring Service Authentication, set this option to the plain text JSON object or full path to `.json` key file that is used to authenticate the service account.

MaxThreads

Key Name	Default Value	Required
MaxThreads	8	No

Description

Defines the maximum number of threads that the connector can initialize and run concurrently in a threadpool.

To configure this property as a connector-wide setting for a non-Windows connector, you must use the `simba.googlebigqueryodbc.ini` file.

PrivateServiceConnectUris

Key Name	Default Value	Required
PrivateServiceConnectUris	None	No

Description

A comma-separated list of base URIs to substitute when accessing Private Service Connect URLs. The following are valid URIs:

- **SERVER_NAME:** The baseline Google APIs service URI, used to perform authentication retries for proxy issues on Windows only. The default value is: `https://www.googleapis.com`.

For example:

```
SERVER_NAME=https://<myprivateserver>.p.googleapis.com
```

- **ACCOUNTS:** The baseline accounts service URI, used only for interactive authentication (hidden OAuthMechanism value 3). The default value is: `https://accounts.google.com`.

For example:

```
ACCOUNTS=https://accounts-  
<myprivateserver>.p.googleapis.com
```

- **OAuth2:** The baseline OAuth 2.0 service URI, used to retrieve access tokens for OAuth 2.0 authentication flows. The default value is: `https://oauth2.googleapis.com`.

For example:

```
OAuth2=https://oauth2-<myprivateserver>.p.googleapis.com
```

- **STS:** The baseline security token service, used to retrieve access tokens for External Account Authentication flows. The default value is: `https://sts.googleapis.com`.

For example:

```
STS=https://sts-<myprivateserver>.p.googleapis.com
```

- **BigQuery:** The baseline BigQuery REST API service, used to interface with the BigQuery data source, via the REST API. The default value is: `https://bigquery.googleapis.com`.

For example:

```
BigQuery=https://bigquery-  
<myprivateserver>.p.googleapis.com
```

- `READ_API`: The host and port required to access the BigQuery Storage Read API service, used to read data from tables via the Storage Read API. The default value is: `bigquerystorage.googleapis.com:443`.

For example:

```
READ_API=bigquerystorage-  
<myprivateserver>.p.googleapis.com:443
```

Note:

The format must be `[Host] : [Port]`, with no protocol specifier or URL components.

Note:

- When the connector is configured to use Service Authentication (`OAuthMechanism=0`), the connector prioritizes the `OAUTH2` URI from the key file specified in the `KeyFile` or `KeyFilePath` property. In order, the precedence is:
 1. `KeyFile{ _Enc }/KeyFilePath{ _Enc }`
 2. `PrivateServiceConnectUris=..., OAUTH2=<YOUR_OAUTH2_URL>, ...`
 3. Default
- When the connector is configured to use External Account Authentication (`OAuthMechanism=4`), the connector prioritizes the `STS` URI from either the configuration file specified in the `KeyFile` or `KeyFilePath` property, or, from the `BYOID_TokenUri` property. In order, the precedence is:
 1. `KeyFile/KeyFilePath{ _Enc }`
 2. `BYOID_TokenUri`
 3. `PrivateServiceConnectUris=..., STS=<YOUR_STS_URL>, ...`
 4. Default
- For more information about Private Service Connect, see "Private Service Connect" in the Google Cloud documentation: <https://cloud.google.com/vpc/docs/private-service-connect>.

Timeout

Key Name	Default Value	Required
Timeout	300	No

Description

The length of time, in seconds, for which the connector retries a failed API call before timing out. The specified value must be an integer. A value of 0 indicates no timeout.

UnsupportedHTAPIFallback

Key Name	Default Value	Required
UnsupportedHTAPIFallback	1	No

Description

When the connector uses fetch workflows not supported on the High-Throughput API, this option specifies whether the connector falls back to the REST API or returns an error.

- 1: The connector falls back to the REST API.
- 0: The connector returns an error.

For information on the BigQuery High-Throughput API, see [High-Throughput API](#) on page 69.

UseQueryCache

Key Name	Default Value	Required
UseQueryCache	1	No

Description

This option determines whether the connector uses the query cache when retrieving results.

- 1: The connector uses cached query results, if they are available.
- 0: The connector does not use the query cache.

For detailed information about cached query results, see "Using Cached Query Results" in the Google Cloud Platform documentation:
<https://cloud.google.com/bigquery/docs/cached-results>.
