Flex Algo and BGP-CT

Julian Lucek
Applications of Flex Algo
Applications of Flex-Algo

In this section, we will describe some key applications of Flex-Algo.

If you would like to know about the underlying protocol machinery, see Shraddha Hegde’s talk from Nanog 81.
• A node can be a member of multiple algos.
• A node announces a different node SID for each algo that it is a member of.
• Separate Shortest Path First (SPF) calculations per algo.
• All nodes are members of the Grey topology. Nodes in one plane are members of Red algo, nodes in the other plane are members of the Blue algo.
“Vanilla” traffic from PE1 is mapped to Grey topology, can go anywhere
We have some traffic from PE1 to PE3 that needs to be diversely routed from other traffic from PE2 to PE4.

- Use Blue and Red algos respectively.
ANOTHER FLEX-ALGO EXAMPLE

Nodes and links can be members of multiple flex-algos

Physical topology

Flex-algo 1

Flex-algo 2
METRIC ACCORDING TO TRAFFIC TYPE

Another application for flex-algo is a situation where different traffic types need to use different link metrics.

For example, for delay sensitive traffic, you want a metric proportional to the latency of the link.

For bulk internet traffic, you want a metric inversely proportional to the bandwidth of the link.

In a given network, the two requirements might conflict!
Normal IGP metric in **blue font**. Bulk traffic uses the *normal IGP*. IGP metrics are configured so that the traffic tends to use the high bandwidth links.

Red flex-algo metric in **red font**. Delay-sensitive traffic uses the *red flex-algo*.

*In this example, all routers are members of the normal IGP and the red flex-algo.*
METRIC ACCORDING TO TRAFFIC TYPE
FLEX-ALGO USING DELAY-METRIC

• In the IGP, on each interface configure a delay-metric (plus the normal IGP metric).
  • The delay metric can either be static, or can be automatically derived from live TWAMP probe packet measurements.

• Configure the flex-algo to use the delay metric.

```
set routing-options flex-algorithm 129 definition priority 100
set routing-options flex-algorithm 129 definition metric-type delay-metric
set routing-options flex-algorithm 129 color 129
```

• In general, a flex-algo can be configured to use one of these metric-types:
  • normal IGP metric
  • TE-metric
  • delay-metric
MAPPING TRAFFIC TO THE PREFERRED TRANSPORT

*Colors* provide a convenient way to auto-map prefixes/services to a particular transport.

For example, mapping a particular VPN to a particular type of TE-tunnel or to a particular Flex-Algo.

It’s a very versatile approach, and also plays an important part in BGP-CT (see later).
A prefix (e.g. plain IP or VPN prefix) with a color community is automatically mapped onto the flex-algo with the matching color. Can also be used to map traffic onto a colored TE Tunnel (SR-TE or RSVP-TE).
SLICING ACROSS TELCO CLOUD AND TRANSPORT NETWORK

- Traffic from green and purple overlay networks (slices) need minimum cost transport.
- Traffic from yellow overlay network (slice) needs low-latency transport.
Key point: DCGW1 puts the traffic for cNF2 onto the Flex-Algo or TE-LSP that has color 200, because the BGP prefix has color community 200.
BGP Classful Transport (BGP-CT)
PE1 wants to send traffic to PE2 in another AS using colored transport. It can reach the local ASBR, ASBR1, using the preferred color of transport.

But when the traffic reaches ASBR2, how does ASBR2 know what color of transport is needed? BGP Labeled Unicast (BGP-LU) has no color awareness!
BGP CLASSFUL TRANSPORT (BGP-CT)

A mechanism for extending color-mapping across multiple ASes or domains.

No need to expose internal topology of a domain to any other domain.

Each domain can make its own choice of transport technology independently of what other domains are using
e.g. RSVP-TE/SR-TE, with or without controller, or Flex-Algo

BGP-CT acts as the “glue” between domains
BGP CLASSFUL TRANSPORT (BGP-CT)

BGP-LU is a very popular way of scaling networks, by only having labeled BGP, and no IGP, between different domains (e.g. core/aggregation/access domains) within an operator (“Seamless MPLS”).

BGP-CT is similar to BGP-LU, except that it has {egress PE, color} granularity, rather than just egress PE granularity.

BGP-CT allows BGP-LU deployments to be upgraded to support color-aware transport.
• PE1 maps prefixes (according to color community) to the matching color BGP-CT label and local tunnel or flex-algo to ASBR1.
• In turn, ASBR2 maps traffic to tunnel or flex-algo to ASBR3 according to the color of the incoming BGP-CT label.

e.g. Color 100 = cheapest cost
Color 200 = minimum latency
### BGP-CT – SOME MORE DETAILS

<table>
<thead>
<tr>
<th>SAFI 76</th>
<th>2:1:10.0.0.1/32</th>
<th>Label: L1</th>
<th>Next hop: PE2</th>
<th>transport-target:0:100</th>
</tr>
</thead>
</table>

| SAFI 76 | 2:2:10.0.0.1/32 | Label: L2 | Next hop: PE2 | transport-target:0:200 |

- **New SAFI for BGP-CT**
- **PE2’s loopback with route-distinguisher**
- **New flavor of route target to carry the color**

10.0.0.1/32: Color 100, Label L1
Color 200, Label L2

PE2: 10.0.0.1
