

We all want healthy children

How can giving the HepB vaccination on the day a baby is born be justified as the CDC schedule¹ specifies? I spoke with a Center for Disease Control (CDC) specialist over the phone who explained to me that it is needed because, "should the baby come in contact with infected blood or body fluids it would not be protected." In practical terms however, the way HepB is transmitted is through dirty needles or coitus, neither of which a baby is subject to. The risk benefit cannot be justified. Everyone agrees that vaccines are not 100% safe.

The Engerix-B[®] vaccine contains 250mcg² of aluminum adjuvant (to increase the body's antibody response) and that far exceeds the government recommended maximum limit of 25mcg³. Injecting aluminum into the (closed) intramuscular/circulatory system of a newborn is likely to cause transmission into the nervous system and brain⁴. This is a very different scenario than exposure to aluminum through the (open) digestive system, where developed kidneys can mostly eliminate it from the body.

A baby's immune system and kidney function are not well developed so delaying the vaccine months or even years seems to be a reasonable choice. However, I am finding parents and doctors being intimidated to adhere to the CDC schedule. Dr. Paul Thomas, M.D. who delays (and sometimes eliminates) vaccines⁵, has an autism rate less than 1/1500 among his 13,000 patients. See his book, "The Vaccine Friendly Plan." The USA autistic spectrum average is 1 in 68 children.⁶ Correlation of the increasing number of vaccinations with increasing numbers of autism, food allergies and seizures does not prove causation but it should mean investigation. The studies normally referred to "proving" vaccine safety did not look at a long enough time span nor the interactive effects of Aluminum, a neurotoxin, and other ingredients. Six countries, Denmark, Finland, Iceland, Norway, Sweden and United Kingdom, do not have a universally immunize against hepatitis B. Pregnant women are screened and the hepatitis B vaccine is provided only to well-defined risk groups.⁷

There were over 67,000 cases of HepB vaccine injury reported since 1990.⁸ But acute viral hepatitis B reported nationwide⁹ (2011–2015) averaged only 3,000 cases/yr. As of July 2017, the government has paid out over \$3.4 billion to the vaccine injured.¹⁰ Considering the difficulty of proving cause, this is an extraordinary large sum. Doctors rarely report vaccine injury to the Vaccine Adverse Event Reporting System: <https://vaers.hhs.gov> and most patients don't know it exists, so there is likely a severe underestimation of injuries.

The CDC owns 57 vaccine patents¹¹ and purchases and distributes over \$4 billion dollars of vaccines¹² under the Vaccines for Children program and therefore has a conflict-of-interest.

The safety level of a preventive medicine must be very high, as it is aimed at protecting people against diseases that they may not contract. Most medical school students sign a "First do no harm" Hippocratic Oath type statement.

The USA needs open, non-threatened discussion and informed consent.

We need our pediatricians and medical doctors to investigate further and sign onto: HepB.info/delayHepB which states:

Given the risks of vaccine injury (over 67,000⁸ from HepB) the CDC schedule calling for HepB vaccination of newborns at birth, 1-2 months, and 6-18 months should be amended to be delayed.

In 1983, a total of 11 vaccines were given. Today, more than 65 vaccines are administered and 140 more are in development. At the same time vaccine exemptions are being removed. According to multiple international treaties signed by our government, they do not have right to decide what can be injected into our bodies. If people don't know and don't exercise their rights, those rights will be lost.
