

## **DELIVERABLE 1.3.3: CALCULATION TOOL FOR ASSESSMENT OF THE RENEWABLE ENERGY POTENTIAL IN PORTS**

Edited by:

Dr. ir. J. van Berkel

Professor at HZ-University of Applied Sciences

Research group  $\Delta$ -power: Renewable Energy in delta Areas

## 9.1 Calculation tool for initial assessment of the potential of renewables

As renewable energy is ambient energy, its potential directly is related to (horizontal) surface area. Following the principles outlined in "1.3.2 Draft method to determine potentials of renewable energy sources in SMS ports", the potential of renewable energy in ports follows from a comparison of energy consumption and energy production.

The energy consumption follows either from an assessment (done within WP1) or from an estimate on the basis of the typology of the port (see table 2.2).

Energy production potential is determined on the basis of available surface area [m<sup>2</sup>] and specific potential (e.g. solar irradiation, [kWh/(m<sup>2</sup>.a)]).

The calculations can be done easily in a spreadsheet. Table 3.1 provides the example for Hellevoetsluis harbour.

*Table 3.1 Calculation tool: spreadsheet to assess the theoretical potential of renewable energy techniques. Example Hellevoetsluis*

	A	B	C	D	E
1					
2				<b>Quantity</b>	<b>remark</b>
3			<b>Current port energy consumption</b>		
4	A	Port electricity consumption [kWh/a]	300000		From Energy audit (Workpackage 1), Helliuss harbour
5	B	Port gas consumption [kWh/a]	0		From Energy audit (Workpackage 1)
6	C	Port heat consumption [kWh/a]	0		From Energy audit (Workpackage 1)
7		<b>Total energy consumption [kWh/a]</b>	<b>300000</b>		Assuming that electricity and heat are equivalent
8					
9			<b>Port characteristics</b>		
10	D	Usable water area of the port (tidal) [m2]	250000		Assuming 50 % for Helliuss Harbour
11	E	Usable land area of the port (solar) [m2]	250000		Assuming 50 % for Helliuss Harbour
12	F	Usable water front length (wave) [m]			N.A. due to unfavourable wave climate
13					
14			<b>Port Renewable potential</b>		
15	G	Solar Thermal [kWh/a]	131400000		E x power density of 60 W/m2
16	H	Solar PV [kWh/a]	37230000		E x power density of 17 W/m2
17	I	Wind [kWh/a]	4380000		E x power density of 2 W/m2
18	J	Wave [kWh/a]			F x 10 kW/m. N.A. due to unfavourable wave climate
19	K	Tidal [kWh/a]			D x 2 power density of 2 W/m2. N.A. due to unfavourable tidal range
20		<b>Total renewable potential [kWh/a]</b>	<b>173010000</b>		
21					
22		<b>Reduction of energy consumption [%]</b>	<b>&gt; 100 %</b>		

As can be seen from this example for Helliuss harbour, Hellevoetsluis:

1. The current energy consumption of the marina is modest: 300 MWh/a, which corresponds to 0,07 W/m<sup>2</sup>.
2. Comparing row H and row I (renewable potential) with the demand (row A) it can be stated that, in principle (theoretically) more than sufficient renewable energy can be harnessed.

Note that this favourable outcome very likely is not representative for a port with industrial activity.

Main advantage of the calculation sheet is that it provides a quick assessment of the potential. After positive indication, a more detailed analysis must determine the actual feasibility.

An example of this procedure is TNO's Energy Potential Scan. It involves a more detailed (and cumbersome) analysis of individual users (companies, buildings) with determination of consumption and renewable production potential.

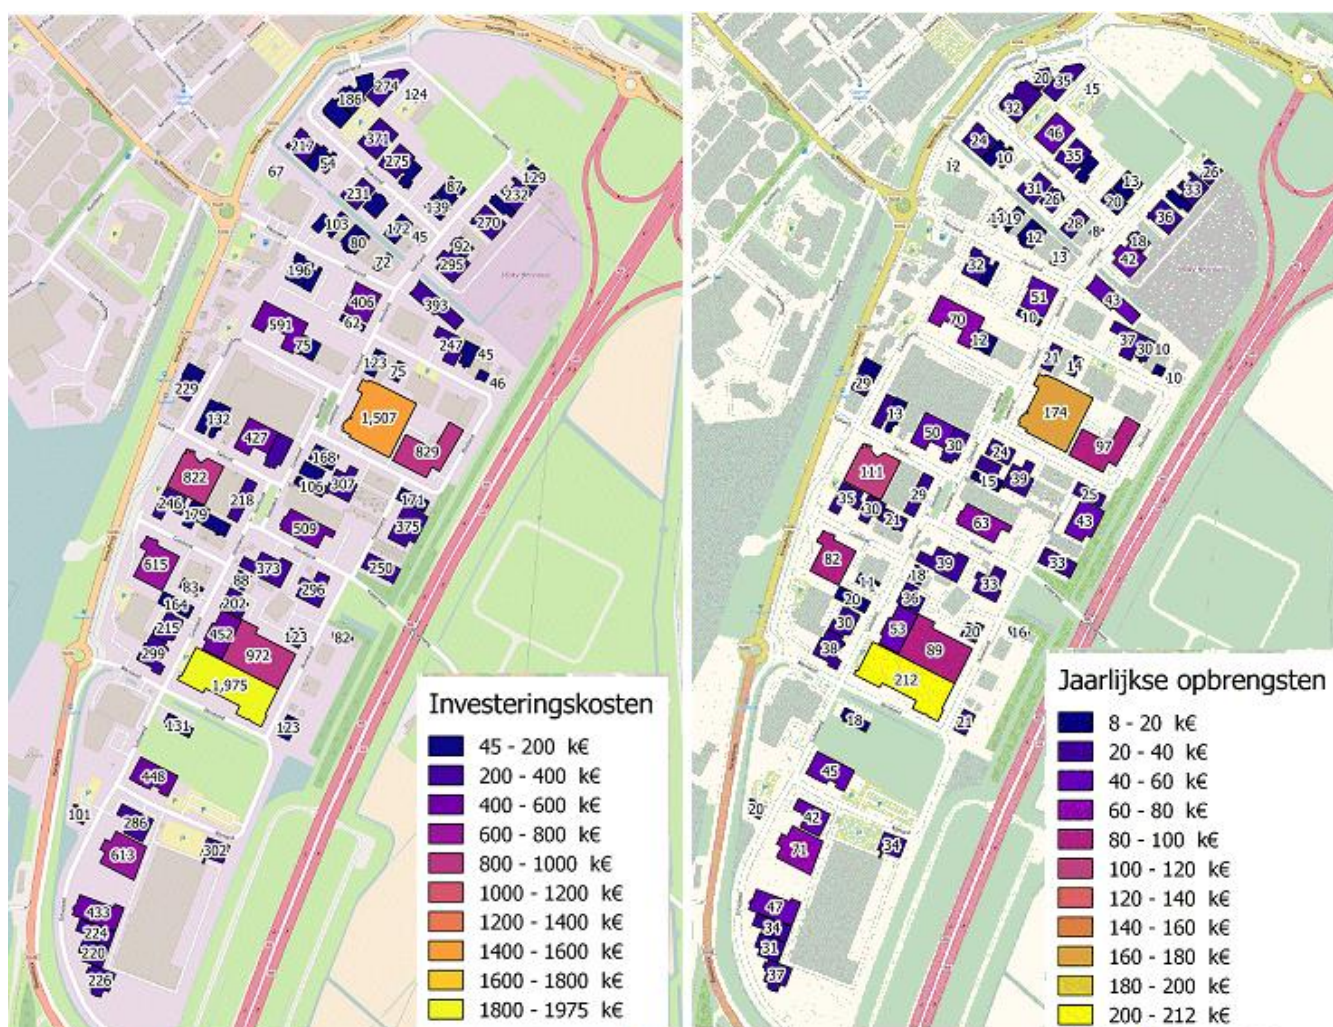

Figure 3.1 Example of TNO's Energy Potential Scan (EPS)-BE+ for the industrial area Kagerweg (IJmond) showing Investment costs (left) and annual benefits (right), reference OD-IJmond.
